**Amputation** of foot for tumour, 70; spontaneous, in uterus, 263; at hip-joint, 305; of thigh for ununited fracture, 464; at hip-joint, Mr. R. Davy on compression of iliac artery in, 704; of thigh for alveolar sarcoma, 737  
**Anæmia**, progressive pernicious, 233, 547, 682; idiopathic, 531; estimated by the hæmacytometer, 752  
**Anæsthetics**, Mr. R. M. Gunn on death from, 335; death from, 729; treatment of threatened apnoea after, 773; in dental surgery, 852; action of on respiratory centre and cardiac ganglia, 872. *See* Chloroform and Ether  
**Analysts**, reports of, 175  
**Anatomy, Surgical**, Mr. J. Chiene's Lectures on, *rec.*, 753  
**Anderson, Dr. McCall**, Lectures on Clinical Medicine, *rec.*, 92  
**Anæcephalous fetus**, Mr. T. W. Hubbard on an, 752  
**Anæmism**, treatment of by iodide of potassium, 305; Mr. Maunier on morphia and a tell-tale as aids to compression, 750  
 — of aorta, 404  
 — of aorta, abdominal, 303; Dr. G. H. Philipson on, 331; diffused after distal compression, Dr. Skerritt on, 405  
 — of aorta, thoracic, 302; Dr. H. Simpson on treatment of, 328; a minute, 464; Dr. J. Cockle on Surgical Treatment of, *rec.*, 528; treated by electro-puncture, 645; Dr. Mahomed on diagnosis and treatment of, 816, 859; treated by distal ligation of arteries, 840  
 — of axillary artery, cured by digital compression, 943  
 — of cerebral arteries, 72, 159  
 — of dorsal artery of foot, Mr. Savory on, 75  
 — of femoral artery, diffused traumatic, 302  
 — of innominate artery, successful operation for, 227; case of, 303  
 — of popliteal artery, 19  
 — of pulmonary artery, 865  
 — of right auricle of heart, 281  
 — of subclavian and axillary arteries treated by rest and restricted diet, 300  
 — of tibial artery, anterior, Dr. W. B. Musbet on, 12  
**Ankle**, excision of, 41; tumour of, 463  
**Ankylosis** of hip and knees, successfully treated, Mr. Folker on, 227; of knee after fracture, 248; Mr. Barwell on antiseptic osteotomy for, 705, 747  
**Annington, Mr. J. W.**, fracture of os calcis by muscular action, 123  
**Antiputrescents**, 306  
**Antiseptic**, thymol as an, 535  
**Antiseptic osteotomy**, Mr. Barwell on, 705, 747; remarks on, 939  
**Antiseptic surgery**, Mr. S. M. Bradley on, 256, 451; Dr. M. Thomas on, 336; in Germany, 342; Mr. J. Duncan on failure of in empyema, 476; letter on, 666; cases of, 863  
**Antisepsis**, action of, 29; in ovariectomy, 419; puerperal, 467  
**Antivaccination statistics**, 648  
**Antivivisection meeting**, 59  
**Anus**, imperforate, 72; plugged by retroverted uterus, 157  
**Aorta**, abdominal, aneurism of, 303; Dr. Philipson on cases of, 331; diffused after distal compression, Dr. Skerritt on, 405  
 — thoracic, aneurism of, case of, 302; iodide of potassium in, 305; Dr. H. Simpson on treatment of, 328; minute, 464; Dr. J. Cockle on Surgical Treatment of, *rec.*, 526; electro-puncture in, 645; Dr. Mahomed on indications for diagnosis and treatment of, 816, 859; treated by distal ligation of arteries, 840  
 — disease of valves of, 13; rupture of valves of, 231; atheroma of, 303  
**Aphasia**, Dr. D. Ferrier on cerebral localisation of, 517  
**Apoplexy**, proper treatment of, 39, 117  
**Apothecaries' Company versus Shenperley**, letters on, 345, 434; *versus* Wiggins, 902; prizes of, 902  
**Apothecary**, definition of, 872  
**Appeal**, 41, 73, 217, 219, 397, 441, 469, 553  
**Arbroath**, water-supply of, 314, 724  
**Ardee**, sanitary condition of, 725  
**Arm**, injuries of, 305; osteoid cancer of, 738  
**Arms**, Dr. G. Roper on treatment of upward displacement of, 255  
**Armstrong, Sir A.**, appointed a magistrate, 495  
**Army**, American, pay of medical officers in, 681  
 — British, medical service of, successful candidates, 216; want of surgeons at the Cape, 236; new regulations for hospital corps, 246; Mr. Hardy's scheme, 272; surgeons in, and riding drill, 27; health of, and the Contagious Diseases Acts, 311; crisis in medical department of, 338, 421; Committee on, 339, 421; vacancies in medical department, 340; memorial of Royal College of Surgeons of Ireland, 345; statement of grievances, 346; clothing of and infectious diseases, 350; medical service of, proceedings in Parliament regarding, 351, 914; Report of Medical Department for 1876, *rec.*, 373; remarks on medical department of, 454, 580, 650, 795; queries by Secretary for War, 460; proceedings of Council of Royal College of Surgeons in Ireland regarding, 498, 541, 581, 799; letters on medical service, 551, 635, 949; return to General Medical Council, 573; reply of School of Physic in Ireland to Secretary of State's circular, 615; reply of King and Queen's College of Physicians, 799; reply of Catholic University, *ib.*; servants of medical officers, 652; letter to Chairman of Parliamentary Bills Committee, 657; Dr. Oliver's equipment, 685; medical nomads, 792

Society, Birmingham Medical Benevolent, annual meeting, 833

— Clinical of London, officers and Council, 99; lupus of face treated by linear scarification and erosion, 114; chorea with epilepsy in adult male, *ib.*; hæmorrhage after operation for cleft palate, 115; spina bifida treated by injection of iodine, 154; Sayre's plaster jackets, 211; erythema multiforme, 212; psoriasis treated by prolonged daily immersions, 230; by ointment of chrysophanic acid, 230, 663; eruption from bromide and iodide of potassium, *ib.*; cancer of breast, 231; tendon ligatures, *ib.*; treatment of transverse fracture of patella, 298; laryngo-tracheotomy for papillomatous growth in larynx, *ib.*; subperiosteal excision of os calcis, 300; excision of lower end of rectum, *ib.*; unilateral atrophy with muscular spasm, 300; aneurism of left subclavian and axillary artery, *ib.*; application of magnets for removal of iron and steel chips from eye, 531; retinitis hæmorrhagica and its connection with gout and venous thrombosis, 532; bilateral paralysis of posterior erector muscles, 662; electrolytic treatment of epulis, 663; hammer-toes and plantar bunions, *ib.*; anomalous mottled rash, 679; caecotrophia folliculorum, *ib.*; ovariectomy in a child, 773; operation for strangulated femoral hernia, 774; ringworm complicated by chloasma, 800; yellow fever, *ib.*; lupus exedens, 802; imperfect right hemiplegia with double optic neuritis, *ib.*

— Epidemiological, variolæ anomala, 15; plague and typhus fever in India, 680; origin of infection, 841; epidemics of small-pox, 913

— French of Hygiene, 29

— Harveian of London, Harveian lecture at, 6; annual meeting, 59; puerperal septicæmia, 157; unsuspected typhoid fever, *ib.*; retroverted uterus in anal orifice, *ib.*; pulse-rate in relation to post partum hæmorrhage, *ib.*; gunshot injury of elbow-joint, 261; drainage of west-end houses and zymotic diseases, 262; hydranmios, 415; thymol, 462; treatment of syphilitic disease of brain and nervous system, *ib.*; unsuccessful ovariectomy, *ib.*; tubercular kidney, 486, 680; intestinal obstruction, 486; relations of diabetes to gout, 487; precipitate labour followed by syncope, *ib.*; diagnosis of abdominal tumours, *ib.*; congenital malplacement of heart, 533; gouty teeth, *ib.*; early diagnosis of stone in bladder, *ib.*; the late Mr. T. C. Jackson, 680; abnormalities of fetal development, *ib.*; caries of cervical vertebra, 773; blepharospasm, *ib.*; epithelioma of rectum, 734; fibroid tumour of uterus treated by sclerotic acid, *ib.*; tumour of left cerebral hemisphere, 843; effects of position on local circulation, *ib.*

— Hunterian, officers, 342

— Liverpool Medical Missionary, annual meeting, 274

— Manchester Medico-Ethical, annual meeting, 267

— Medical of Cardiff, annual meeting, 200; officers and Council, *ib.*

— Medical of College of Physicians of Ireland, alternate paralysis, 233; facial paralysis, 303; fatal typhus, with hyperpyrexia, 304; the late Drs. Stokes and Churchill, 666; obstructed circulation, *ib.*; cholera in Dublin in 1866 and its relation to geological formation of district, 807; small-pox in Dublin, 913

— Medical, Liverpool, officers, 100

— Medical of London, treatment of broken nose by forcible straightening and use of retentive apparatus, 301; annual dinner, 381; medals, *ib.*; officers and Council, *ib.*; annual oration, 657, 669; port-wine mark, 665

— Medical of Manchester, removal of metatarsal bone of great toe, 233; salivary calculus, *ib.*; progressive pernicious anæmia, *ib.*; hemiplegia, with enlargement of paralysed parts, *ib.*; pseudo-hypertrophic paralysis, *ib.*; plica Polonica, 418; gastrostomy for stricture of œsophagus, *ib.*; localisation of cerebral disease, *ib.*; removal of tongue, *ib.*; cerebral tumour with aphasia, *ib.*; progressive muscular atrophy, 488; fibroid phthisis, *ib.*; intrathoracic tumour, *ib.*; impetigo figurata, *ib.*; urethral brush, *ib.*; malignant disease (?) of liver in a boy, *ib.*; restoration of lower jaw after resection, 737; amputation of thigh, *ib.*; splint for knee-disease, *ib.*; suture-needle, *ib.*; lamp for mercurial fmnigatio, *ib.*; small child, *ib.*; tumour of cerebellum, *ib.*; palpebral nevus, *ib.*; scarlatinal endocarditis, *ib.*; syphilitic liver, *ib.*; contributions to the pathology of brain, *ib.*; removal of penis, *ib.*; osteoid cancer of arm, 738

Society, Medical Microscopical, final meeting, 164

— Medical of Worcestershire, annual meeting, 235

— Medico-Chirurgical of Edinburgh, excision of knee, 70; disease of femur, *ib.*; amputation of foot for tumour, *ib.*; congenital malformation of leg, *ib.*; Addison's keloid, *ib.*; malposition of testes, *ib.*; supernumerary auricle, *ib.*; stricture of œsophagus, *ib.*; treatment of ununited fracture, 71; injury of head with anomalous symptoms, *ib.*; tendon reflex, 305; amputation at hip-joint, *ib.*; redex paraplegia, *ib.*; injuries of the arm, *ib.*; scirrhus tumour of orbit, *ib.*; tumours, *ib.*; penetration of orbit by knitting-needle, *ib.*; salivary calculus, *ib.*; aneurism, *ib.*; goitre, 734; excision of tongue, *ib.*; disease of shoulder-joint, *ib.*; removal of ulna, *ib.*; cancer of lip and jaw, *ib.*; examination of ear, *ib.*; diseases of kidney, *ib.*; Sanitary Association, 735

— Medico-Chirurgical of Glasgow, popliteal aneurism, 19; hydrophobia, *ib.*; obstruction of bowels, 418; hydatids, *ib.*; midwifery forceps, 463; arrest of uterine hæmorrhage, *ib.*; treatment of acute rheumatism, 680; Pott's disease of spine, 736

— Medico-Chirurgical, Leeds and West Riding, annual meeting, 833

— Medico-Chirurgical, Sheffield, removal of upper jaw without external incision, 71; extraction of cataract by shallow lower flap, urinary test-case, *ib.*; piece of glass in bronchus, *ib.*; pyæmia, 71, 72; case of scalping, 71; removal of portion of silver catheter from bladder, 72; deformed forearm and hand, *ib.*; calculus removed from urethra, *ib.*; intracapsular fracture of neck of femur, *ib.*; imperforate anus, *ib.*; rupture of uterus in third month of pregnancy, *ib.*

— Medico-Chirurgical, West Kent, meetings, 323, 400, 806; mercury in inflammation, 741

— Meteorological, winter climate of English seaside health-resorts, 341

— Mutual Dissection, 581

— Northumberland and Durham Medical, prevalent diseases of district, 19, 488; pathological specimens, 19; papers, 19, 188; traumatic cerebral hæmorrhage, 488; adenoid tumour removed from groin, *ib.*; extreme example of conical stump, *ib.*; mass of calculeous fragments, *ib.*; fractured spine, *ib.*; empyema in child, *ib.*

— Obstetrical of Dublin, fibrous polypus, 262; influence of uterus in eye-diseases, *ib.*; treatment of post partum hæmorrhage, *ib.*; milk fever, 404; horse-kick kidney, 740; cerebro-spinal meningitis, *ib.*; amphoric resonance in solidification of lung, *ib.*; scrofulous ulceration of leg, *ib.*; effect of chronic osteitis in scrofula, *ib.*; double ureters, 741

— Obstetrical of London, calcified fibroid tumour of uterus, 15; secondary puerperal hæmorrhage, *ib.*; general dropsy in foetus with hypertrophy of placenta, *ib.*; complete rupture of perineum, *ib.*; meningecele complicating labour, *ib.*; double vagina and uterus, *ib.*; extra-uterine pregnancy, 15, 157; removal of large uterine myomata by abdominal section, 15; rupture of uterus, 157; effect of perchloride of iron on uterus, *ib.*; malignant uterine disease, 158; cancer of uterus, 414, 732; epithelial cancer of uterus, 414; tumour connected with uterus, *ib.*; inversion of intestine through umbilicus, 415; report of University Lying-in Hospital, Montreal, *ib.*; deputations to General Medical Council, 601; new metro-tome, 604; fibro-cystic disease of uterus, *ib.*; tubes for injecting uterus after parturition, *ib.*; unicorned uterus, *ib.*; traction by lower jaw in head-last cases, *ib.*; protracted labour, 665; rupture of foetal head, 732; cancerous polyp removed during pregnancy, *ib.*; cystic disease of foetal kidney, *ib.*; congenital syphilis, *ib.*; rupture of uterus, *ib.*; repair of female bladder and urethra, *ib.*; rupture of uterus, 733; puerperal convulsions, *ib.*; effusion of blood into peritoneal cavity, 842; uterus during menstruation, 843; fracture of cranium in newborn child, *ib.*; Cæsarean section, *ib.*; pregnancy complicated with malignant growth in vagina and rectum, *ib.*; membranous dysmenorrhœa, *ib.*; treatment of chronic inversion of uterus, *ib.*

— Pathological of Dublin, dislocation of spine, 72; sacular aneurisms (Virchow), *ib.*; lesions in morbus coxæ, *ib.*; the late Dr. W. Stokes, 137; spontaneous amputation, 263; melanotic carcinoma, *ib.*; atheroma of aorta, 303; cure of thoracic aneurism, *ib.*; vast abdominal aneurism, *ib.*; diaphragmatic hernia, 417; disease of knee-joint, 665; peculiar multiple fracture of femur, *ib.*; ovarian tumour, 487; intracapsular fracture of femur, *ib.*; carcinoma of liver, *ib.*; tuberculous in a lioness, *ib.*; enteritis fatal on eleventh day, 666; "black quarter" in calf, *ib.*; chronic pleuropneumonia, atheromatous degeneration, 845; muscular anomalies, *ib.*; carcinoma of abdominal viscera, *ib.*

— Pathological and Clinical of Glasgow,

ovarian tumour, 306; genu valgum, *ib.*; paraffin splints, *ib.*; intrathoracic aneurism, *ib.*; putrefaction and antiputrescents, *ib.*; officers and Council, 399; tumour of ankle, 493; urethral calculus weighing six ounces, *ib.*; calculus encysted near root of penis, *ib.*; early ovum, *ib.*; rotary lateral curvature of spine, *ib.*; case of croup, *ib.*; sarcoma of eye, *ib.*; acute tuberculous, 736; early foetus, *ib.*; diphtheritic exudation, *ib.*; pathology of lungs, *ib.*; malposition of teeth in rabbits, 737

Society, Pathological of London, annual meeting, 64; officers, *ib.*; bromide of potassium eruption, 68; general hyperostosis, with osteoarthritis, 69; osteitis deformans, *ib.*; sarcomatous tumours in bones, with hyperostosis, *ib.*; dermoid cysts along branchial fissures, 165; paralysis agitans, *ib.*; colloid cancer of rectum, *ib.*; diaphragmatic hernia, *ib.*; phos-phatic diabetes, *ib.*; aneurism of cerebral arteries, 159; rupture of aortic valves, 231; prostatic tumours removed by lithot my, *ib.*; impacted fracture of shaft of femur, 232; bacillus of splenic fever, *ib.*; cancer of throat, 232, 261, 841; recurrent sarcoma, 232; plunging of superior mesenteric and femoral arteries, *ib.*; caries of spine, *ib.*; sarcoma in muscle of leg, *ib.*; congenital obstruction of common bile-duct, 233; tumour of ovaries, 230; cysts from peritoneum, *ib.*; cystic disease of thyroid, *ib.*; malformation of heart, 261; imperfect muscular development of septum ventriculorum, *ib.*; thrombosis of vena cava and portal vein, *ib.*; aneurism of right auricle, *ib.*; melanotic liver, *ib.*; ulceration of large biliary calculus from gall-bladder into duodenum, *ib.*; dilatation of heart and aorta from old spinal disease, 391; lymph-sarcoma, *ib.*; worms in heart and œsophagus of dog, 842; rare form of psoriasis, *ib.*; nevus complicated with molluscum, *ib.*; disease of spinal cord in diabetes, *ib.*; hypertrophic lupus, *ib.*; renal calculus containing indigo, *ib.*; honorary members, 455; diseases of lymphatic system, 461, 529; leukæmic viscera, 461, 530; lymphadenoma and leucocythæmia, 461, 462; lymphadenoma, 720; hyperplasia of axillary glands with leukæmia, *ib.*; intestines from case of lymphadenoma, *ib.*; splenic leukæmia with carcinoma, *ib.*; idiopathic anæmia, 531; ulceration of bowel in connection with granular kidney, 841; renal calculus of mixed carbonate and phosphate of lime, *ib.*; spontaneous disintegration of calculi in bladder, *ib.*; microscopic characters in tissues affected by measles, *ib.*; epithelioma of female lip, 842; cancerous ulcer of skin, *ib.*; French millstone makers' phthisis, 844; carcinoma of orbit, *ib.*; tumour of sclerotic, *ib.*; cerebral embolism, *ib.*; anatomy of dysidrosis, *ib.*; elongated cavity in spinal cord, *ib.*; ovarian cysts from bodies of twin infants, *ib.*; spontaneous rupture of œsophagus, 845; aneurism of pulmonary artery, *ib.*; filarion disease, *ib.*; elephant axis of clitoris, *ib.*; polypus from nose, antrum, and orbit, *ib.*; colloid cancer of breast, *ib.*

— Pharmaceutical of Ireland, election of president, 726

— for Relief of Widows and Orphans of Medical Men, quarterly meeting of directors, 59; annual meeting, 686

— Royal, nomination of fellows, 581

— Royal Medical Benevolent Fund of Ireland, annual meeting of Belfast Branch, 241; officers, 270; annual meeting, 845

— Royal Medical and Chirurgical, microscopical anatomy of chronic inflammation of surface of tongue, 67; maternal impressions, *ib.*; favus, 68; rodent ulcer, 155; proportion of red corpuscles in the blood in some skin-diseases, 156; simple atrophic sclerema, *ib.*; writer's cramp, 224; anæmia, 267; ankylosis of knee-joints, with shortening of femora, 298; officers and Council, 309; award of Marshall Hall memorial prize, 389, 316; annual meeting, 345; report of President and Council, *ib.*; change of time of meeting, 346; president's address, *ib.*; stone in bladder of male adult, 381; skin in tinea tonsurans, 486; parasites of tympanic membrane, *ib.*; myxœdema, 626; anatomy of kidneys and urinary casts, *ib.*; ophthalmoplegia interna, 627; ophthalmoplegia externa, 601; transverse calcareous film of cornea, *ib.*; arterial hæmorrhage from wounds of face and neck, *ib.*; resuscitation of the apparently dead, 724, 723; pathology of hæmophilia, 772; pathological traces of pulmonary hæmorrhage, *ib.*; brain in congenital abscess of one half, *ib.*; abscess within thorax, *ib.*; anatomical remedy against respiratory obstructions, 772; spirillum fever of Bombay, 889; aneurism of aorta and innominate, subclavian, and carotid arteries, treated by double distal ligature, 840; intussusception, *ib.*; fatal purpura after administration of iodide of potassium, 841

— Surgical Aid, remarks on 379, 421, 802

— Surgical of Ireland, restoration of eyelid after excision for intractable ulceration, 262; ex-

traction of foreign body from left leg, 263; deformities of bladder, with experiments, *ib.*; the late Dr. Stokes, 304; exostosis of the lower jaw, *ib.*; displacement of ulna backwards with T-shaped fracture of humerus extending into elbow-joint, *ib.*; ovarian cyst, *ib.*; supposed fracture of great trochanter, *ib.*; deformities of bladder, *ib.*; excision of knee-joint, 417; ways in which fever begins, 418; amputation of thigh for ununited fracture, 464; minute aneurism of aorta, *ib.*; multiple polypi in uterus, *ib.*; Farre's tubera circumscripta of liver, *ib.*; excision of lip, *ib.*; rupture of tendon of gluteus maximus, 487; fracture of spine, 740; green tea as an antidote in poisoning by opium, *ib.*; epithelioma of lip, *ib.*

— Sussex Medical Friendly, annual report, 457

Soda, bicarbonate of, treatment of burns by, 280, 294

— salicylate of, Dr. F. H. Daly on, 87; in acute rheumatism, 348

— silicate of, treatment of erysipelas by, 452

Soldiers, attendance on wives and children of, 383

THE following Reports have been published in the present volume.

The Antagonism of Aconite and Digitalis. By Dr. J. M. Fothergill. In JOURNAL of May 4th.

The Physiological Action of the Chinoline and Pyridine Series of Compounds. By Dr. J. G. McKendrick. In JOURNAL of May 4th.

# BRITISH MEDICAL JOURNAL:

BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EDITED BY ERNEST HART.

LONDON: SATURDAY, JANUARY 5, 1878.

## LECTURES ON THE INFECTIVE PROCESSES OF DISEASE.

*Delivered in the Theatre of the University of London.*

By J. BURDON SANDERSON, M.D., LL.D., F.R.S.,  
Professor of Physiology in University College; and Superintendent of the Brown Institution.

### LECTURE II (*continued*).—*Etiology of Septicæmia.*

WE have seen that it is easy to prepare from putrid infusion of muscle an extract which, while perfectly soluble in water, possesses the toxic property of the original material in such intensity that a very small dose of it (less than half a grain), if infused into the blood-stream of a dog, is sufficient to produce fatal septicæmic effects. We have also seen that there is good reason for thinking that these effects are entirely independent of the direct action of septic organisms, inasmuch as they are not attended with the development of such organisms in the body of the poisoned animal. If we were to limit our view exclusively to such considerations as these, we should be not unlikely to swing round to a way of thinking which might be defined as the very opposite of the germ-theory, and to express ourselves in this way: "You see, after all, that these gentlemen who have been talking about germs, Pasteur, Tyndall, Roberts, Lister, etc., are all under a delusion. These supposed organisms, whatever may be their nature, whether aerial or aquatic in their habits, whether actual or hypothetical, have nothing to do with septicæmia, and, by inference, nothing to do with disease."

To meet this tendency, I will ask your attention to the evidence by which we may assure ourselves that, although bacteria are not the agents in septic infection, they are, nevertheless, the producers of the septic poison, and that the mistake, if any mistake have been committed, consists in this: not in stating that bacteria are of pathological importance, but in asserting that because A produces B and B produces C, therefore, C cannot be produced unless A is present. It would, I think, be erroneous to say that the yeast-plant is the agent in the production of the evils of intemperance, and it is a mistake to say that bacteria are the agents in the production of septicæmia; but just as, if there were no yeast-plant there would be no drunkenness, so, if there were no bacteria there would be no septicæmia. I have now to bring before you the evidence that this is so.

As I stated yesterday, all the earlier experiments on septic infection were made with putrid infusions of the tissues of animals or plants. As all such liquids must necessarily contain proteid material, it was thought that the specific virulence must attach to some particular chemical product of the putrefactive disintegration of albuminous compounds. It was, therefore, suggested by Virchow that the proper way of searching for the septic virus was first to determine what these products were, and then to test each of them by physiological experiment. But this method is much more easily proposed than carried out, for chemists are not as yet in a position to give us very exact information as to the nature of these products. What we find in animal putrid infusions when we examine them is this. If we slightly acidulate the liquid and boil it, we find that it contains common albumin. In the uncoagulated liquid, we throw down a further quantity of proteid material by the addition of alcohol—this being in the state of peptone. The unprecipitated liquid, partly aqueous and partly alcoholic, contains two well-known bodies, leucin and tyrosin, the presence of both of which may be readily recognised by their several characters. In addition to these, various volatile products of definite chemical constitution

are present, one of which, the body indol,\* distinguished by its peculiar odour recalling that of feces, can be prepared in larger quantity and with greater facility by the action of septic bacteria on albumin than in any other way. All of the bodies I have mentioned, peptones, leucin and tyrosin, indol, and the rest, are known to occur in the small intestine as products of the action of the pancreatic ferment, so that there is a very striking resemblance between the action of the pancreatic ferment and putrefaction. The resemblance, however, by no means implies identity; for, although bacteria are always present, and must, therefore, in actual digestion, mix their fermentative influence with that of the proper digestive ferment, it has been proved by the most careful experiment, that, so far as relates to the conversion of the proteids of food into the soluble and diffusible peptones, the process of pancreatic digestion can begin and be completed without them. The ultimate products, however, are not precisely the same when bacteria are excluded, the most characteristic difference being that the volatile products I have mentioned, and particularly indol, do not appear when albumin or fibrin is subjected to the digestive action of the pancreatic ferment under conditions which either exclude the septic organisms or inhibit their development.†

So far as our present knowledge reaches, none of the known chemical products of the putrefactive disintegration of albuminous compounds can be indicated as the cause of the toxic action of putrid infusions; for in respect to each of them we have experimental evidence that, when separately introduced into the organism, in such quantity as would correspond to a poisonous dose of the septic liquid of which it is a constituent, it produces no toxic effect whatever. The inference is, therefore, suggested that the poison is not any product of the septic disintegration of proteid bodies, but a something which is much more intimately associated than any of them are with the existence and growth of the ferment-organisms themselves.

This inference has been fully justified by experiment. It has been shown by Professor Bergmann that the septic poison can be produced by the action of bacteria on material which contains no albuminous compound. He found—and we are now familiar with the fact by repeated experiments—that, if you grow bacteria in the cultivating liquid to which I previously referred, of which the composition is given in the table,‡ the first crops of bacteria are inert; but eventually you obtain a product which possesses all the virulence of putrescent animal or vegetable infusions, notwithstanding that the original liquid contained only sugar, ammoniac tartrate, and certain inorganic salts.

Let us endeavour to realise what happens. We have, to begin with, virtually a solution of ammoniac tartrate; for it can be shown that it is all that is wanted at the outset. Into that solution you introduce at one side, say a bit of glass which has not been calcined and of which the surface is consequently contaminated, *i. e.*, beset with germinative particles. The vegetation takes its start from the surface of the glass. One after another bacteria emerge into existence and visibility, and multiply with a rapidity which you can easily calculate, on the datum that each becomes two within about an hour after its birth.

Having our bacterium, how does it manufacture its virus? In order to obtain an answer to this question, I will ask your attention to the following experimental results, which, irrespectively of their bearing on the present question, are of value for the additional evidence they afford of the fundamental proposition of this lecture, *viz.*, that septicæmia is not due to the direct action of living bacteria on the blood and tissues.

\* Indol (C<sub>8</sub>H<sub>7</sub>N) is a crystallisable body, obtained by the reduction of certain derivatives of indigo, which fuses at 52 deg. C., and is volatile at a very low pressure. It has no toxic properties; but its solution in water, when introduced into the circulation, gives rise to the appearance of indican in the urine in corresponding quantity. See M. Jaffe, Ueber den Ursprung des Indicans in Harnes; *Chem. Centr. Bl.* *Medicin. Wissenschaften*, 1872, p. 2; and Konkol Jasne-polsky, Ueber die Bildung von Indol, *u. s. w.*; *Plüger's Archiv*, vol. vii, p. 75.

† Nencki, *Ueber die Zersetzung der Gähr- und Ferment-Substanzen*, Bern, 1865, p. 31.—Kühne, *Erfahrungen und Bemerkungen über Enzyme und Fermente*, *Uebersuch. des Physion. Institutes der Universität Heidelberg*, vol. i, part iii, p. 13, of the reprint. Kühne has lately found that, when an artificial pancreatic digestion of albumin or fibrin is conducted with the addition of thymol, no indol is formed, although the process is not otherwise interfered with.

‡ The cultivation liquid contains, in 100 cubic centimetres, 10 grammes of cane-sugar, 1 gramme of ammoniac tartrate, and 0.2 gramme of potassic phosphate.

Some years ago, Dr. Hiller,\* one of the most energetic and able of the opponents of the germ theory, made an experiment which has been the subject of much discussion. Having succeeded in collecting a considerable mass of bacterial material, that is, of bacteria obtained from various fluids in advanced putrefaction, on a filter, he washed the mass, just as one washes a precipitate, a great number of times; then diffused the material which had been so washed in distilled water, and injected it in repeated doses into the circulating blood of animals. The injections were entirely without effect. Hiller next proceeded to inoculate himself with the same material, and again without effect. The advocates of bacteria at once objected to Hiller's experiment, that the bacteria, not being accustomed to distilled water, were so injured by the repeated washings that they had lost their activity. The criticism, however, might just as well have been spared; for it afforded Hiller the opportunity of proving by experiment, which was of course easy enough, that the washed bacteria were as lively and as capable of development as ever.

But there is another way in which inactive bacterial liquids can be prepared: a way to which I have already adverted. In any cultivation of bacteria in a nutrient solution, the first crop (if I may use the expression) is always inert. It is not until the bacteria have gone on for many days dividing and dividing, that they begin to develop their poisonous properties, at all events, in appreciable quantity. This can scarcely mean anything else than that the mode of vegetation changes; viz., that the bacteria first formed have their place taken by others of which the form and the physiological endowments are different. Every one who is familiar with the growth of bacteria in cultivating liquids knows that there is a marked difference in appearance between the first and the subsequent growths, the former consisting mostly of rods (bacteria proper), which appear early, the latter of spheroids or micrococci. They differ not only in form, but also in the fact that, whereas the rods are endowed with great mobility and appear to act independently, as if each had a consciousness of its own, the latter are held together in masses by transparent interstitial substance (glea), and usually form a scum or pellicle on the surface of the liquid.

The meaning of these facts seems to be this. It is obvious that, in every liquid in which successive generations of organisms grow in the way I have described, each generation must alter the composition of the liquid; and that this change may consist, not merely in the discharge into the liquid from the bodies of such organisms of the "waste products" of their vital processes, but also (in case any of the earlier generations, instead of continuing to live, are disintegrated) of the products of such disintegration; so that, in the latter case, it is quite possible that a liquid which was at first non-albuminous may, as the process goes on, contain an appreciable quantity of proteid matter. That any such formation of plasma actually takes place, cannot be asserted. All that we know on observation is, that the later generations differ, as regards their morphological characteristics, from the earlier, and that they alone possess toxic properties; so that two processes must go on side by side: a change in the composition of the liquid, and a corresponding change of the organisms which grow in it.

The question whether the chemical changes of the soil determine the morphological characters of the vegetation, or are determined by them, must remain open; for the scanty facts which we have before us admit of being explained either way consistently with what is known as to the origin of organisms. Thus it may be supposed either that there exist originally in the liquid a variety of latent germs which, as the soil gradually changes its characters, emerge in succession into activity, the moment of germination of each being determined by the adaptedness of the soil for its development; or that the successive generations of organisms are organically continuous with each other, the forms first produced being gradually modified under the influence of the gradual change of environment. Both of these theories are open to objection. Against the first it might be advanced that we have as yet no sufficient evidence of the plurality of germs;† against the second that so rapid a process of evolution is scarcely consistent with our experience of the process by which other organised forms are evolved. In relation to our present inquiry, it is of comparatively little moment which of the two views is accepted, so long as it is clearly understood that the relation between the evolution of *organised form* and the concomitant changes of *environment* is of such a nature that, while neither can go on without the other, neither can be said to be the cause of the other.

I mentioned a while ago, that the fact of the gradual development

of toxic properties in liquids which contain no nitrogenous constituents excepting ammonium salts was first discovered by Bergmann. The same line of inquiry has been pursued further by several of his pupils; and I am now going to ask your attention to some recent researches undertaken by one of them, Dr. Anders,\* for the purpose of determining how far it holds true as regards these originally non-albuminous liquids, that (as has been shown to be the case as regards putrid infusions) the poisonous action is exerted independently of the vital endowments of the organisms which produce it.

Of the various methods of experiment employed by Dr. Anders for this purpose, the one which yielded the most interesting results was the employment of antiseptics, using the term in its physiological sense as applicable to any body which destroys or annuls the physiological properties of septic organisms and of their germs. But before I proceed to discuss the application of this method to the question at issue, it will be necessary to say a word or two as to the relative values of the various bodies known as antiseptics in destroying the vitality or arresting the development of septic bacteria.

The best known antiseptics, and those of which we are most certain, are chlorine, potassic permanganate, carbolic acid, and salicylic acid, and lastly, the camphor-like products obtained by the distillation of the essential oils of thyme and of caraway—thymol and carvol. We know by experiment that these bodies differ very materially in antiseptic, or as it is sometimes called, germicidal power. My friend Dr. Buchanan Baxter found that in a cultivating solution, of which the composition agreed very closely with that on the table, chlorine produced sterilisation in the proportion of 1 in 100,000, potassic permanganate in the proportion of 1 in 10,000, and carbolic acid only when in the proportion of 1 per cent. About the same time that Dr. Baxter's researches were published, an entirely independent investigation of the same question was conducted by Dr. Bucholtz.‡ His researches extended over a larger number of disinfectants (although they did not include potassic permanganate), and had this additional advantage, that the value of each disinfectant was determined with reference to two properties, viz., first, that of destroying the germinative power of the liquid used, and secondly, that of preventing or checking the further growth of the bacteria already growing in it. The results are exhibited in the table. It is seen that, as regards the relative values of chlorine, sulphurous acid, and carbolic acid, they agree very closely.

At the time that Dr. Baxter made his experiments, salicylic acid had scarcely taken its place as an antiseptic. It appears, indeed, to have been first experimented on with a view to its germicide properties by Bucholtz, who was led to think that it would probably be an antiseptic by the consideration of its constitution and chemical relations. Bucholtz tells us that his experiments were already concluded, when he was anticipated by the publication of the well known paper of Kolbe, on Salicylic Acid, in *Erdmann's Journal* (vol. x, p. 89). Kolbe discovered that salicylic acid had a very remarkable power of preventing, even when added in a proportion which did not exceed 0.05 per cent., the fermentation of beer, and this led him to make a number of experiments as to its influence in arresting putrefaction, from which it appeared that meat, urine, milk, and other things could be kept exposed an indefinite time when small percentages of salicylic acid were added to them.

It was on the basis of these facts that Dr. Anders proceeded in his investigation of the toxic action of a liquid of the same kind as that which yielded the poisonous scum to which I before drew your attention. It was necessary to show by experiment, first, that the material to be used was toxically active; secondly, that the dose of salicylic acid to be added to it was without physiological action; thirdly, that the liquid in question was completely sterilised (*i.e.*, that a cultivating liquid, to which a few drops of it were added, remained transparent although placed in a warm chamber at the proper temperature); and lastly, that it was still active, producing death in a few hours with the usual symptoms, after the addition of the antiseptic.

I have only to add that similar experiments were made with chlorine, of which the results were equally unequivocal. Here, as in the case of salicylic acid, it was shown conclusively that a dose of chlorine which was more than sufficient to destroy, and actually did destroy, the vitality of the living organisms present, left the virulence of the liquid unimpaired.

\* Anders, Giftige Wirkung von durch Bakterien betriebene Nahrflüssigkeit, *Deutsche Zeitschrift für Chirurgie*, vol. vii, p. 1.

† Bucholtz, Antiseptica und Bakterien, *Archiv für Experimentelle Pathologie*, vol. iv, p. 1. Bucholtz found that, while carbolic acid prevented the development of bacteria when added to his cultivation-liquid in the proportion of half per cent., the same result was produced with 0.15 per cent. of salicylic acid, with 0.1 per cent. of carvol, and 0.05 per cent. of thymol. The percentages of the same bodies required to sterilise a liquid already containing bacteria were, for carbolic acid, 4 per cent.; for salicylic acid, 0.3 per cent.; and for carvol and thymol, each 0.5 per cent. It was for this reason that salicylic acid was selected by Dr. Anders for his experiments.

\* Hiller, Untersuchungen über die Bacterien in ihre Beziehung zum menschlichen Organismus, *Med. Centralblatt*, 1874.

† This objection is deprived of whatever weight might otherwise attach to it by the 1 cautious experiments of Professor Lister, which appear to prove that even a single drop of water may contain a great variety of germinal particles.

## ABSTRACT OF CLINICAL LECTURE

ON A

## CASE OF NASO-PHARYNGEAL POLYPUS.

By WILLIAM S. SAVORY, F.R.S.,

Surgeon to St. Bartholomew's Hospital.

THE form of tumour called polypus is more common in the region of the nares than in any other part: here it varies in structure and site. While from their shape they all are properly termed polypi, some—and these are the most frequent—have a simple loose fibro-cellular structure, with much fluid in the meshes—the familiar mucous, gelatinous, or, as it is now termed, myxomatous polypus; some are firmly fibrous—fibromata; while others, consisting of the more immature elements of connective tissue, are sarcomata. I need not add that these several kinds of polypi vary in their nature: some are innocent, others are recurrent, or even malignant. Let us, however, be clear about this. Every one knows that even the simplest and most innocent—the common polypus of the nose—very frequently recurs after removal. It is apt to grow again and again, and its complete and final extirpation is at times a matter of very great difficulty; while even the sarcomatous polypus—the kind consisting chiefly of immature forms, the texture which emphatically suggests recurrence—may yet, provided it can be entirely removed, even to the base of its stalk, and the surface from which it grew destroyed, never return. Indeed, in these polypi, beyond all other tumours, this seems to be a point of the first importance. When, after an apparently satisfactory removal, the nostrils again become plugged with the ordinary gelatinous polypus, either (which is only too likely) some fragment of the original stalk has been left, or other small polypi, which, having been compressed by the first, could not expand, as soon as they obtain space rapidly fill up the nostril. Pott, in his chapter on Nasal Polypus, very clearly points this out (see works by Earle, vol. iii). I fancy these common polypi are more often multiple than they are usually supposed to be, because after the entire removal of a large one with a typical shape and perfect stalk, I have often seen the apparently vacant nostril rapidly occupied by several very small and distinct growths; and for this reason it is always well to employ an astringent for some time after an operation. On the other hand, we see cases in which when a polypus possessing a structure suggestive of very ugly inferences is cleanly and thoroughly swept away, it never recurs. Of course, there is a wide difference in the liability to recurrence of these various kinds, determined by their nature and independent of the mode of removal; and perhaps, a yet more important distinction, in the fact, that while the more innocent forms, although recurring for many years, are not wont to trespass beyond their original site, the worse forms are sadly prone to extend their base of growth, and to invade and occupy without scruple adjacent parts. They may grow from any portion of the surface, either of the nares, sinuses, or pharynx. They often, in their progress, expand, and sometimes even pass through bone and intrude on the brain (see Preparation 2210a—fourth volume of *Pathology*—in the museum of the Royal College of Surgeons).

Another fact which, in more than one way, is of great clinical importance, is that these several kinds of polypi are apt to spring from different parts, so that the situation of a polypus, or more precisely of the surface from which it grows, is strongly suggestive of its structure and character. Every one, for instance, knows how the common gelatinous polypus affects the turbinated bones, and how usefully, when we proceed to remove them, we are guided by this knowledge; whereas the polypi which occupy the pharynx are fibrous or sarcomatous, these latter springing far more indifferently from any portion of the surface of the naso-pharyngeal region. Their favourite sites are the posterior border of the nares, about the edges of the pterygoid plates, sometimes the margin of the septum or the upper wall of the pharynx, the under surface of the body of the sphenoid or basilar portion of the occipital.

Some one may perhaps ask why I have not mentioned cancer among the forms of polypi. Because I do not think that cancer, in its proper sense, forms the structure of polypi, strictly so called, whether nasal, pharyngeal, or naso-pharyngeal, to which form of tumours these remarks apply. You meet, of course, with cancer in the nose and pharynx. It will grow into and destroy those parts, but not as a polypus; not, I think, as a pyriform tumour with a well defined stalk, springing either from the mucous membrane or the fibrous tissue be-

tween it and the bone. The stalk of the firmer kinds of polypus is usually, indeed, directly continuous with the periosteum.

Now, I must not here enter at any length into the question of treatment of these various kinds of polypi. The principle is the same in all: to remove as cleanly as possible the whole of the growth, to detach thoroughly the base of its stalk—to destroy its roots, as some say. In order to secure its thorough extirpation, we do not think of attacking the bulk of the tumour; its neck and base are the parts at which we aim. We may grasp the pedicle with strong forceps, or secure it by a ligature, or use the knife or *écraseur*, or cautery, or carry out the principle in other ways: but the operation is never satisfactory when the polypus is brought away piecemeal or torn and mangled. The simple object is, I repeat, to bring the whole thing away at once by its neck, and to leave a bare surface, with no fragment projecting beyond the level of the surrounding mucous membrane. In the case of the more doubtful forms, it is well to cauterise the surface afterwards.

In accomplishing this, lies the whole art of removing these polypi; and I need not tell you that the degree of difficulty of this operation varies widely in different cases. In the nose, we are guided by our knowledge of the parts apt to be involved, sometimes assisted by the gentle and cautious use of a probe, with which we may define the neck. When they occupy the upper part of the pharynx, we examine with our finger passed up behind the soft palate, assisted usually by a director or something like it, passed through the nostril. But from whatever part the tumour may grow, the difficulty of defining and commanding it is, I think, always invariably increased by any previous attempt at extirpation. When these polypi have been rudely attacked and injured, their usual form is altered; the distinction between the base of the tumour and adjacent parts becomes obscured. You cannot then so clearly distinguish between what ought and what ought not to be there. It is certainly most satisfactory to have to do with polypi which have not been previously interfered with. When they recur after removal, it almost always happens that they are removed with more difficulty than at first. Seldom, very seldom, can a second or third growth be so neatly detached as the first one. I think the base usually spreads more widely with each recurrence, and the surrounding membrane is apt to become more and more changed.

In order, then, to carry out our plan efficiently, we must, of course, be able not only to reach, but also in some measure to command, the base of the polypus. The first step, therefore, is to define, as well as we can, its point of attachment. Now, in illustration of the extent to which it is sometimes necessary to proceed, let me ask your attention to the following case.

Ernest Scott, aged 13, apparently a healthy boy, but small for his age, was brought to the hospital in May 1874, with a polypus in the nose and pharynx. The right nostril was tolerably free, but, when a director was carried along the left nostril, it came into contact with a firm foreign body at the back part, which prevented it from passing into the pharynx. The soft palate was pushed somewhat forward, and appeared unduly convex. When the finger was carried up behind it, a well-defined polypus could be made out, occupying much of the space behind the posterior nares, principally on the left side, and attached to the upper portion of the margin of the septum and the roof of the left side.

A few days after admission, the boy being under chloroform, a strong pair of forceps was passed along the left nostril, and, guided by the finger behind the soft palate, the blades were separated and carried on each side of the neck of the growth. This being firmly grasped and twisted, a large portion of the mass was torn away and brought through the nostril. A second and third attempt removed all that remained or could be detected, and the boy very speedily recovered from the operation. A week or two afterwards, a second and very thorough examination was made of the region, but no traces of the polypus could be discovered, and the boy left the hospital seemingly quite well.

Mr. Butlin examined the tumour, and described it thus: "Very firm and tough, presenting to the eye the appearance and to the touch the characters of firm fibrous tissue. Section streaked occasionally with red or purple. The masses were irregularly lobulated, apparently not encapsuled. Microscopical characters: sections, carefully examined, appeared to consist of wavy fibrous tissue, but mingled with round, oval, or even stellate cells in various proportion. The character of the connective tissue varied very much, even in different parts of the same section. Each of the polypoid growths was covered with a thick layer of tessellated epithelium, several cells deep." He adds: "It is probable that these tumours are outgrowths of the mucous and submucous tissues of the interior of the nostrils. No distinct follicles, lined with epithelium, were observed, although it might have been expected that adenoid structures would exist in them. It is not unlikely that they will recur."

We saw no more of the lad for a year, until May 1875, when he returned, now fourteen years old, in a very sad state; and told us that he had been suffering from a recurrence of the disease for the last three or four months. He looked ill and had evidently lost flesh. It was at once evident that a large and formidable mass occupied a great portion of the left nostril, some part at the back of the right, and the whole of the upper region of the pharynx. The left nostril was visibly expanded. On opening the mouth, the soft palate appeared forcibly thrust forward. It was very convex and extremely tense, and below its free border the convex surface of a smooth firm pale tumour could be seen. This so entirely blocked up the naso-pharyngeal region, that the finger could not at any part be carried up to the side of it, nor could any instrument be passed far into the nostril. Moreover, the outline of the left side of the face differed from that of the right. It was fuller, the cheek was wider, and further examination showed that this depended on an extension of the growth laterally behind the left jaw and past the pterygoid plates, until it could be obscurely felt as an ill-defined mass below the zygoma. There had been no hæmorrhage from the tumour, but it was apt to bleed a little when touched by a probe or other instrument in the nostril. There was no glandular enlargement. The local effects of this very ugly tumour were distressing enough. The poor boy swallowed with difficulty, he articulated indistinctly, he was very deaf, especially on the left side, and—gravest result of all—his respiration was embarrassed. This latter effect was gradually increasing. When first admitted, the respiration was noisy and laboured. During sleep, it became so difficult that he was continually awakened, and at length could only doze for short periods, and the noise he then made disturbed the whole ward.

Now, it was very clear that, if this recurrent polypus were left alone, the boy had not long to live; and the important question was, in what way an attempt should be made to remove it. Was there any chance of detaching it by the plan previously adopted—by any kind of manipulation through the mouth or nostril? Was it practicable to get sufficient command of the tumour this way, assisted by the division of the nostril, or soft palate, or both? We thought not. It seemed to us highly improbable that by this means I could get at the base; and, moreover, even when in far more favourable circumstances I removed it in this way, it recurred. Then what further should be done? The tumour was behind the left upper maxilla, and if I previously removed this, there was every probability that I should freely expose the mass. But would nothing short of this severe measure suffice? Might I not, as some have done in similar cases, cut away the back part of the hard palate, and thus get room? But the patient was so small and the mass so large, that it was probable that even this might prove inadequate, and it hardly seemed wise to attempt any means that did not offer a strong chance of success. Therefore, we decided to remove the bulk of the upper maxilla and the palate; not absolutely the whole of the left bone, but all of it except the orbital and nasal portions. But again the question occurred, might we not adopt a proceeding which has occasionally found favour at the hands of some eminent surgeons on the Continent? Might we not, short of completely removing the upper jaw, detach it from adjacent bones, turn it upward or aside awhile, get in this way sufficient space to deal with the tumour and then replace it, and so, after all, save this important bone? Well, the proposition was to me, in this instance, a tempting one. If I could only have done this, then, indeed, there would have been but little to qualify the advantage of the operation. But on considering the case in all its bearings, we came to the conclusion that I ought not to run the risk which it involved. In the first place, as before mentioned, I was loath to adopt any operation that did not offer a strong probability of success, and I doubted whether by this plan, after all, I should obtain sufficient room to reach the attachment of the tumour. Remember that in the child the maxilla is not only absolutely but relatively smaller than in the adult. Again, every fraction of space is important in this operation, not only in enabling one to command the growth, but because the avulsion of such a mass is, as we well know, liable to be followed by profuse hæmorrhage, and, chiefly on this account, it was desirable to see as much of the region as possible. Lastly, time is a matter of moment in such an operation, and, therefore, I was anxious to avoid all unnecessary complication, to make the steps as simple as practicable. So on June 9th, I began by removing the upper jaw through a vertical incision made from the nostril to the lip, then carried upward round the ala to the root of the nose and outward below the margin to near the external angle of the orbit. The facial artery was thus divided at its distal extremity only, and no ligature was required. The soft and hard palate having been divided in the usual way, the body of the maxilla was cut through obliquely from immediately below the zygoma upward and inward into the nostril, and thus detached. Then passing

my finger backward, I could just make out the neck of the polypus, but in order to command the morbid growth satisfactorily, it was necessary to remove the pterygoid plate and to divide the soft palate vertically through the upper three-fourths of its extent. After this had been done, the neck of the polypus, which was now well in hand, could be securely grasped with very stout forceps, and by two or three forcible twists and wrenches it was torn away. It was generally pyriform, and consisted of two principal and two or three smaller lobes, all pendulous. The largest lobe, of the size of a common egg, lay to the left and came out of the pterygo-maxillary and temporal fossa. As the tumour came away, an artery of some size, deep in the left side, no doubt the internal maxillary, bled freely. This was at once secured, and no other vessel needed a ligature. As soon as the tumour was removed, I could feel, denuded to a large extent of its periosteum, the under surface of the body of the sphenoid and the basilar portion of the occipital. On this site, the stalk of the polypus was implanted, and hence it grew downward and then outward into the pharynx and behind the left jaw. I touched the surface of the bones with a hot iron, put a silver suture through the upper angle of the partially divided soft palate, and then accurately adjusted the flap of the integument.

The boy bore the whole operation remarkably well, and never for an instant appeared faint. He was sometimes only partially under the influence of chloroform, for while he was on the table before the operation there was so much difficulty of breathing that it was not thought prudent to push chloroform far. He lay very quiet after the operation, showing no signs of distress, and having taken a few teaspoonfuls of wine and beef-tea, sank into a heavy, but natural, sleep. When I saw him in the evening, he was still sleeping soundly and naturally. The respiration calm and deep, and the pulse 110. As the sister said, No wonder, for he wanted sleep, having had, from the impediment to respiration, no long interval of sound sleep since his admission. During the last few days, especially, his respiration had been extremely embarrassed. On the night preceding the operation, he was suddenly aroused by a choking fit, and until he was enabled to sit up suffocation appeared imminent.

The boy recovered directly and rapidly, without any untoward symptoms. On the third day, the twisted and some other sutures were removed; and on the next, the rest, except that in the palate, which was left for some days longer. The slit in the soft palate united perfectly throughout; and a week after the operation, the boy was sitting up. I have seen him repeatedly since. Within the last month—now two years and a half from the removal—I have carefully examined the region without detecting any sign whatever of recurrence of the tumour. The boy is quite well and strong, and has grown rapidly. He wears an artificial palate on the left side, which is of great service to him, especially in articulation; but when it is removed, the hole that it covers will hardly admit a finger. As is usual after excision of the upper maxilla, there is very little difference in the contour of the two sides of the face.

I am again indebted to Mr. Butlin for a description of the polypus. "The growths were more abundant than on the first occasion, but otherwise presented almost precisely the same characters. In minute structure, they were alike. They showed various forms of connective tissue more or less highly nucleated; but in these, rather less cell-growth."

There are two or three points in relation to large operations in this region to which I should, in conclusion, like to call your attention. These operations are, you know, dangerous ones—dangerous during the performance. A patient may die on the table under the surgeon's hands. Nay, I may say that they are never quite free from this danger even with the utmost skill and care. Therefore, in such cases especially, you can never afford to throw away the slightest chance. Now, in order to avoid danger, it is well to know where it lies. In these operations, a patient may die from loss of blood or from suffocation—more likely from these two causes combined. The heart's action is weakened, and the respiration becomes embarrassed. In the first place, which is the best position for the patient during the operation? Should he recline or sit? In my opinion, the objection to the horizontal posture is so grave that it far outweighs all advantages on the score of lessening the degree of faintness. Blood is apt to find its way into the larynx and air-passages—a risk unfortunately increased by the use of anaesthetics; and the danger of this terrible evil is undoubtedly augmented when the patient lies with the head low. For this reason beyond all others, I prefer to have the head and shoulders well raised. The patient may lie on a couch rather than a chair; but the head and chest should be more nearly vertical than horizontal.

But the next matter is, I think, one of still more serious influence. In these operations, although anaesthetics are employed, yet it is usually impracticable, without undue risk, to keep a patient during the

whole time so thoroughly under their influence that he is perfectly passive. Of course, the operator may be embarrassed in his work if the patient be not thoroughly under control. Of course, means must be adopted to prevent any untoward movement. I need hardly say that the head must be fixed, and, if necessary, the action of the limbs restrained. But the surgeon, while legitimately securing every advantage for himself, must see that he does not lay upon the patient any additional danger. Now, my meaning is, that I have great objection, in these operations, to binding patients firmly down. It is very easy for the surgeon to secure the patient's arms closely to his side by towels or bandages; but reflect for a moment on the effect of this. If you were required to limit the movements of respiration, how could you more effectually accomplish that end than by drawing the arms forcibly down and fixing them tightly to the sides? And think, too, of what a free respiration means in such a case; not only how the circulation and respiration are associated, but of the urgent need from time to time of forcible expiratory efforts to clear the glottis and adjacent parts. Therein, indeed, lies the prime objection to anaesthetics; but their use saves so much in another way, that some extra risk may be justified on this account. But, for the sake of a little, if any, more convenience to the operator, ought a patient at such a crisis to be burdened thus? A couple of assistants will suffice to control all troublesome movement without mischief. I dare say some may consider this unnecessary refinement; that nothing can turn upon so trivial a point. Are you quite sure of this? And, if there be any question on the matter, there can be no doubt about the duty of the surgeon.

Lastly, the patient's danger may be increased from the interest of those around. As the operation proceeds, in a natural anxiety to see everything, those looking on, or even assisting, are apt to crowd closely around the table, and thus largely to deprive the patient of what just then he very much wants—fresh air. A hint before on this point, to be repeated if necessary, may not be amiss. I bring these points forward, not because I deem them important beyond all others, but because I think they especially are apt to escape attention.

## CLINICAL OBSERVATIONS ON OVARIOTOMY.

By J. THORBURN, M.D.,

Professor of Obstetric Medicine in Owens College; Obstetric Physician to the Manchester Royal Infirmary; etc.

GENTLEMEN,—You have just recently seen—that is to say, those of you who are not engaged in anatomical or *post mortem* work—two very satisfactory cases of ovariectomy. Before your interest is absorbed by other cases, I propose to make a few clinical observations upon these. There are so many interesting abdominal tumours in our wards or out-patient *clinique* at present, that I want to fix a few points regarding each of them on your memory before they pass from our sight.

The two ovarian cases recently operated on are those of Mary Hughes, aged 45, and Susan Hoggard, aged 26, in the Dorcas Ward. You have heard from time to time full details of their past history, and have seen how a diagnosis was arrived at. Time does not allow me to repeat these details now, and I shall, therefore, briefly say that both cases were well marked examples of multilocular cystic disease; that each had been three times tapped, at rapidly lessening intervals; that each was free from other organic disease, as far as could be ascertained. Adhesions were slight in the case of Hughes, but more numerous in that of Hoggard; and, as they were very high in the abdomen, and required some force to break them down, I was not without anxiety on the score of secondary hæmorrhage.

I hope both cases may now be considered as convalescent. Now, I have been considering what are the chief points to which I can most profitably call your attention. The ordinary steps of the operation of ovariectomy you will find in every recent text-book; you have had leisure to study them, and two very good opportunities of seeing them. Judging, moreover, from the present state of our out-patient *clinique*, there will be no lack of similar opportunities in the future. Instead, therefore, of recapitulating these details, I will confine myself to one or two points which I have been trying to think out for myself, as far as my opportunities have permitted.

1. I have come to the conclusion that the operation of ovariectomy is beginning to be far too rashly undertaken, or, at any rate, in too early a stage of the disease. When ovariectomy was a new operation, those who practised it were often accused of selecting their cases, *i.e.*,

of operating only on those cases which appeared likely to be good ones, and refusing to operate on those which, although they might possibly save a patient from inevitable and almost immediate death, were more likely, by their issue, to discredit the operation and the operator. If Sam Slick's statement that there is a good deal of human nature in man be true, these accusations were probably not quite unfounded. But, as the operation has been more largely studied and practised, and especially as it has been gradually found out that the unpromising cases, *i.e.*, the cases of women past middle life, reduced, not in size, but in apparent vigour, by formerappings, with a peritoneum accustomed to the presence of tumours and trocars, are by far the most favourable ones, this kind of selection is becoming a thing of the past. But another, and, in my opinion, as great a danger is arising. Everybody is now supposed to be capable of performing ovariectomy, and the *début* of a successful case among the patients and friends of the operator is so great, that such cases are eagerly sought after, and a curious page of medical history would be furnished by a collection, if such a thing were possible, of the results of ovariectomy during the last ten years in purely private practice. The splendid lists of successful operations which have been published by our great English and American ovariectomists are not without danger also to younger men who aspire to follow in their wake. During the past twelve months, I have tapped three healthy and otherwise vigorous women for ovarian tumour, and in each case have counselled considerable delay before having recourse to ovariectomy; in all these cases, the urgency of the friends has led to other advice, to operation, and to death. I have just heard also, within the last few days, of the case of a young lady who, after ailing for some time, was found to have ovarian tumour. Immediately she was taken to London for a consultation, operation was decided on, and, in less than three weeks, she was diagnosed, consulted over, operated on, and buried. Let me give you my very decided opinion that ovariectomy should not be so rapidly and rashly undertaken. I would advise you, in every case, to try one tapping at least; it will help in diagnosis, and it may cure. I have cured one case in this way which I thought was a growing multilocular cyst. If your patient be comparatively young, and otherwise in fair condition, try a second tapping at least, and carefully ascertain the rate of growth. If, after this, you are satisfied that life is beginning to be jeopardised by the exhaustion of tapping, by wearing pain, or otherwise, then ovariectomy may be performed with hopefulness and with greater probability of another addition to the splendid *résumé* of increased years of human life referred to with justifiable pride by Mr. Spencer Wells at the late meeting of the British Medical Association.

2. Another point to which I may allude, in connection with the operation, is the size of incision advisable. The question of a long or a short incision has been much discussed formerly, and statistics have been drawn up as to their relative value. Such statistics have, in my opinion, no importance whatsoever. The larger incisions were made, as a rule, for larger or more adherent tumours, or for cases more difficult in other ways; hence the short incisions were pretty sure to have the best of it. I cannot see myself what difference an inch or two more can make in the danger of an incision of the kind, and I have seen, both in my own practice and in that of others, great danger from adhesions which might have been much better treated with a larger wound, and from dragging at, instead of enlarging, the opening. Even in the case of unilocular cysts, there are often adhesions which require a good opening to treat them safely. I would advise you, then, in almost every case, to make an incision of fully four to five inches, and not to hesitate to enlarge it at once as freely as seems necessary to command a good view of what you are doing.

3. The treatment of the pedicle is a subject which has from the first been much discussed. You will find in Mr. Wells's work a most temperate and thorough discussion of the various methods that have been used, including its retention outside the peritoneum by the clamp, and its treatment within the peritoneum by ligatures, *écraseur*, acupressure, cautery, etc.; and his vast experience has led him to adopt the clamp for the great majority of his cases. I am bound to say, however, that the use of a strong well tied silk ligature, cut short and allowed to fall into the abdominal cavity, has so far commended itself to me. The late Dr. Tyler Smith had a very fine series of cases treated in this way: it was this which induced me to try the plan, and it is so superior in handiness, and in every way, to my mind, so much more simple, that I fancy I am likely to continue its use until I have met with a case where I find inconvenience from the after-presence of the ligature, or until I have been unfortunate enough to meet with one where a ligature of my own tying has proved insufficient to prevent hæmorrhage. I have unfortunately seen a very promising case lost in this institution from the slipping of the pedicle out of the clamp, which certainly looked as if nothing could have escaped from it. Bear in mind, how-

ever, that very powerful and pure silk, *i.e.*, animal tissue, well carbolicised, should be used. This must perforate the stump of the pedicle, so that it cannot slip off at the end, and must then be tied in two separate portions. If the pedicle be very thick or broad, three or even four portions must be tied separately. If these precautions be observed, sufficient force may be used in tying to render any danger from shrinking an impossibility. A touch with the galvanocautery might add to the apparent safety where the operator is timid; the ordinary cautery is apt to leave behind it some *débris*, which is at any rate unnecessary.

4. The influence of a hospital atmosphere for evil upon cases of ovariectomy has been so clearly proved that it can hardly admit of any doubt; and possibly the Infirmary Board, when it has overcome some of its more pressing difficulties, may be induced to provide us with a separate building or thoroughly detached ward for such cases alone. It is not, therefore, with the view of disputing the dangers incurred from hospitalism that I point out how, nevertheless, with reasonable care, much may be done to obviate these dangers. We are now in a building which is acknowledged on all hands to be, in many sanitary respects, as bad as it can be, and where erysipelas has frequently been peculiarly rife. During the short time that I have been connected with it, there have been ten cases of ovariectomy: three by Mr. Southam, two by Mr. Heath, and five by myself; of these, eight have recovered with hardly a bad symptom, and there has been no septicæmic mischief. One, already referred to, died from the slipping of a clamp, and one (my own) from secondary hæmorrhage from numerous pelvic adhesions.

5. Antiseptic treatment, in its relation to ovariectomy, is a subject full of immediate interest. The intimate connection between all forms of septicæmia and certain germs, and the destructive effect of carbolic acid and other agents upon the latter, so ably advocated by Mr. Lister, seems to have passed into the region of absolute fact. Though not yet convinced, even by the exhaustive researches of my friend Dr. William Roberts, or by those of my old Edinburgh Infirmary colleague Mr. Lister, that there may not be some *tertium quid*, chemical, electric, or otherwise, which may stand in the relation of cause, or at any rate of promoter, both of sepsis and of germ-growth, the practice dependent on the theory that the one is the cause of the other seems so consonant with all present available hypothesis, and so approved by clinical facts, that I consider it utterly unjustifiable to deny our patients its fullest advantages. I will not enter into the question as to whether, in ordinary surgery, the processes of dressing advocated by some are not so complicated and unnecessarily troublesome as to deter many from the use of antiseptics—*ne sutor ultra crepidam*—but, in ovariectomy, I am sure that simpler and more effective, *i.e.*, more antiseptic, methods will suffice. The plan I have adopted in twenty-five successive cases of ovariectomy has been this: after tying the pedicle, I thoroughly smear it with carbolic glycerine and drop it into the cavity of the abdomen. This imparts a strong carbolic atmosphere to the peritoneal cavity, thereby increasing the effect of carbolicised sponges, ligatures, etc. The well known effect of glycerine upon the uterus, which you have seen in our ward practice, is, no doubt, exerted also on the pedicle and adjacent parts; a good deal of their redundant moisture is absorbed, and the natural process of shrinking is hastened. In these last two cases, I have also used the carbolic spray apparatus, and my friend Mr. Lund has kindly directed its application. After passing a sufficient number of silver sutures across the abdominal wound, I next smear every interstice of it with the same carbolic glycerine, not forgetting its free application to the peritoneal edges. I then tighten and twist the sutures, and apply a piece of lint dipped in carbolic glycerine. Some long adhesive straps, a clean napkin, and a binder complete the process.

How or when the wound heals, I cannot exactly tell you: for I do not look at it for ten or twelve days. In the case of Hughes, it was first looked at on the eleventh day; the stitches were taken out as free from discharge as if they had been imbedded in a turnip or other vegetable body. To-day, we will open up the dressings of Hoggard, and you will find the same result. All that is required is to remember that the cicatrix consists of very new tissue; and that you must provide, by adhesive straps and binder, for many weeks against the giving way of this new tissue; indeed, I consider such precautions more than usually necessary, seeing that you have, while hastening the adhesive process, diminished some of the inflammatory action which is usually supposed to make adhesion more complete. It is hard to say how far this real antiseptic treatment has modified the mortality of these twenty-five cases; but I will give you the results, premising only that, in every case, I have followed out the rules I have tried to impress upon you. I have not operated on a single case which did not appear to have a certainty of death within two, or at the most three, years; and in two of them death was immi-

nent from peritonitis within a few hours. Six of these twenty-five cases have died—one from hæmorrhage—I might almost say on the operating-table—two from peritonitis, which existed at the time of operation (in one of these I operated by gas-light; the symptoms were so urgent); one from hæmorrhage from adhesions in the pelvis, about forty-eight hours after operation; one from shock on the night of the operation; and one from pneumonia coming on on the fourth day after operation, after the patient had twice managed to escape from her bed in the search for stimulants. The most vivid imagination could not possibly trace the existence of septicæmia in any one of them.

If the clamp were used, this mode of procedure would not be quite so easy; but I think it would be quite available if the whole were well saturated with the carbolic glycerine, and if, as suggested by Dr. Marion Sims, some cotton-wool were placed above it, to prevent, by its filtering properties, the entrance of germs from outside.

Time will not allow me to touch on any further points; but there are one or two others to which I hope to draw your attention after our next case.

## ABSTRACT OF HARVEIAN LECTURES

ON

### THE MECHANICAL SYSTEM OF UTERINE PATHOLOGY.

*Delivered before the Harveian Society of London.*

By GRAILY HEWITT, M.D., F.R.C.P.,

Professor of Midwifery and Diseases of Women, University College; and Obstetric Physician to the Hospital.

#### LECTURE III.

CONTINUING the analysis of uterine symptoms, amenorrhœa was mentioned as occasionally produced by compression in cases of uterine distortion. Sterility is necessarily produced by such compression of the uterine canal as prevents the passage of fluids. Another cause of sterility in these cases is the altered condition of the lining of the uterus when retention of secretions occurs; this damaging the products of conception.

*Abortions* have as their most common cause flexions of the uterus. Repeated observation of the frequency with which abortion and flexion are witnessed in conjunction, first led the author to this conclusion. Other causes of abortion, syphilis, lead-poison, accidents, mental emotions, account only for a comparatively few cases. Retroflexion is already admitted as a cause of abortion. It is not well known that ante flexion is a very common cause. Considering the part the uterus has to play in pregnancy, it is not surprising that decided distortions should have a disturbing influence. The organ is then more exposed to disturbance by straining efforts. The tissue-alterations produced by flexion must also interfere with its extensibility; and the condensation, puckering, and atrophy present at the seat of flexion are decidedly inimical to the healthy progress of pregnancy. Further, actual disease of the decidua may result (cases by Slavjansky). In many cases, as pregnancy advances, the flexion is relieved, but otherwise abortion generally occurs. Natural cure in this way is easier in ante flexion than in retro flexion cases.

*Reflex Phenomena.*—Of these, sickness or nausea stands first. This symptom is almost universally observed, more or less marked, when the uterus is diseased. It may be very slight, or it may be so severe and continuous that finally there is a fear of starvation occurring. It may be looked for almost as commonly as dyskinesia. In dysmenorrhœa, sickness is often a very prominent symptom. This nausea and vomiting are reflex in nature, the irritation being in the uterus. In some cases, like symptoms are observed from dislocation and compression of the ovary. Organic disease of the uterus also may occasion it. Putting aside these causes, we find that the most common uterine irritation is flexion of the organ. Indeed, severe reflex uterine symptom is invariably due to flexion. It is worse when the flexion is conjoined with considerable uterine congestion. In the slighter continuous forms, it is frequently conjoined with very undue softness of the uterus. The erect position, even sitting in such cases, induces nausea, in consequence of a slight temporary increase of the flexion so produced. Other reflex symptoms, hysteria, convulsions, etc., were next briefly discussed.

*Disorders of the Function of the Rectum and Bladder* are witnessed with great frequency in cases of flexion. When the axis of the uterus is more or less at right angles to the proper one, the rectum is often obstructed, defecation is hindered in retroversion, and flexion especially

so. Occasionally the fundus uteri invaginates the rectum, and acts as a complete ball-valve. Diarrhoea is sometimes the result of friction of the bowel, produced by flexion. Pain in defecation is another common symptom; prolapsus of the bowel occasionally results. As regards the bladder, friction of micturition is most commonly the symptom, and ante-flexion the cause. Pain, after emptying the bladder, is due to this also. Retention of urine is most commonly caused by retroversion or retroflexion.

*The Changes in the Uterus* were next considered. Change of shape and position has been shown to be the most important of these changes in congestion or engorgement of the uterus. It has a very intimate connection with change in shape; hence, in fact, diversity of opinion. Finally, the question really is, what is the cause of the uterine congestion? Congestion pure and simple is not perhaps rare, but it is rarely witnessed. It may give rise eventually to hypertrophy, but it does not usually occasion marked symptoms. It is when conjoined with flexion that it assumes clinical importance. Congestion is inevitable when the uterus is compressed at its centre; which happens more or less when the uterus is flexed. Klob and Thomas also take this view. The two extremities of the uterus, or one more than another, exhibit this result in particular cases. That mere congestion does not occasion flexion, has been ably argued by Dr. John Williams. That flexion is only important when conjoined with congestion—a view advocated by many, is erroneous. No doubt the advent of congestion aggravates the suffering. It is equally certain its removal is a blessing to the patient; but the fact that the congestion disappears or undergoes material diminution, by simply straightening the uterus, shows what is the real relation of the connection between the two. It is sufficient to carefully watch the behaviour of the uterus in such cases to become convinced of the importance of the flexion. There are many varieties of congestion; the uterus attacked by it being in different states in different cases. Mere softness of the uterus must not be confounded with it, though a soft uterus is very liable to become congested. The manner in which local hypertrophies of the os originate from long-standing flexion, congestion at these situations, were next described. "Congestive hypertrophy" is the term proposed to describe the changes hence resulting. ("Areolar Hyperplasia," Thomas). The other changes observed at the os—swelling, turgescence, redness, abrasion of epithelium, etc., have a close connection with congestion, produced as above described. "Chronic inflammation", which is the term which has been applied to the conditions giving rise to these changes, is more accurately described as "congestion".

The varieties of uterine distortions come under two principal heads: a. Anterior flexion; b. Posterior flexion. Lateral flexions are rare. The local secondary effects are very important: the undue thickening of the uterine wall at some situations, the great thinning of it at others. It may be found as thin as brown paper at the internal os. Hence the great difficulty of absolute cure in very long-standing cases.

Disorders of innervation have been already discussed.

*Peri-uterine Inflammation.*—On this latter subject, the only remark for which there is space is that, in some cases, an cedematous effusion is liable to occur near the uterus as a result of displacement.

*Principles of Treatment.*—"Preventive medicine" is the medicine of the future. From this point of view, the previous considerations suggest important generalisations. The mechanical diseases of the uterus being the most important, and such disease almost never occurring except when the uterus has become greatly weakened in consequence of the general condition of the body being at a low ebb, it follows that the greatest care should be exercised in nourishing and sustaining the strength of the body as a preventive measure. Exercises and exertions will have to be regulated. Pain following exertions will not be lightly regarded. The effects of long-continued nausea will not be overlooked. As regards the cure of the diseases, first, it must be admitted that all are not alike. Duration of the disease alters the curative aspect of cases, the consistence of the uterus also, the soft uterus being more easily curable. The great object is to restore the uterus to its proper shape: 1. By positional treatment, which is capable of doing very much, and sometimes all that is required. This fact is very important, as it enables us to treat rationally, and without necessity for local measures, cases of commencing disease in young women. Instances of this were given. The horizontal position is best, either prone or supine, according to the nature of the case, *i.e.*, whether the flexion is backwards or forwards. In severe cases, it is not enough, but is still absolutely necessary, otherwise failure will result; and, as a part of the treatment may have to be more or less insisted on for a long time, the knee-elbow position is a further aid. 2. Mechanical internal treatment is required in long-standing cases. Pessaries, by which pressure is made upwards, in front of or behind the uterus, are of the greatest service, aided by positional treatment. For backward flexions, modifications of

the Hodge pessary; for forward flexions, the author's "cradle" pessary are recommended. Pessaries ill-fitted are worse than useless. If the uterus be hard, the sound must be also frequently employed to aid in the unbending. Tents also effect this object. Uterine stems, improved by Meadows, Bantock, Chambers, and others, are of great assistance in some cases. The congestion which forms so important an element in cases of this kind is generally at once relieved by straightening the uterus, by position, by a pessary, or by the sound.

The general treatment is of the utmost consequence. One of the principal merits of the system of uterine pathology now expounded is, in the author's opinion, the explanation offered of the process by which health passes into diseases, and why the sound uterus becomes predisposed to injury from accident, or, more slowly, by the debilitating influence of semi-starvation. A generous diet is always required. Frequent small meals are necessary, especially is animal food required. Tonics are useful. Fresh air, but not long walks or long drives, unless in the semi-horizontal position. Baths, frictions, and other hygienic measures, are useful adjuncts.

In conclusion, expressing his regret that time did not admit of even an arrangement of the facts which he would have been glad to bring forward in support of the arguments employed, Dr. Graily Hewitt said: "My appeal is confidently made to unbiased intelligent observation for confirmation of the facts on which these conclusions are based. How far I have succeeded in my endeavours to deduce from clinical facts a rational and intelligible system of uterine pathology, it must be for you to determine."

## CHEIRO-POMPHOLYX.

By WARREN TAY, F.R.C.S.,

Surgeon to the Hospital for Skin-Diseases, etc.

It is with great regret that I help in any way to prolong a most unnecessary and unfortunate discussion as to a "simple question of priority"; but I feel compelled to do so by the kind of evidence Mr. Tweedy adduces, namely, his own familiarity with Dr. Fox's teaching since 1870, and a conversation he had with Mr. Hutchinson in 1873, leaving any one to infer that, whilst Dr. Fox recognised a certain skin-disease as peculiar in 1870, Mr. Hutchinson was just taking notice of it in 1873. Now, I have no wish to detract in the slightest from the credit due to Dr. Fox for recognising the disease as far back as 1870, or for publishing his description, in 1873, under the term "Dysidrosis"; but, on the other hand, I must carry my memory back six years further than Mr. Tweedy does, namely, to 1864, when the portrait published by Mr. Hutchinson was taken. I distinctly recollect the fact of the artist being sent to Nottingham; I saw the portrait when finished, and Mr. Hutchinson talked to me (and others) about the features of the disease on many occasions. There are others besides myself who can assert that the essential clinical features of the description given by Mr. Hutchinson in his *Atlas* formed subjects of conversation at the London Hospital, the Hospital at Blackfriars, and elsewhere, whenever the portrait was shown, or a case bearing any resemblance presented itself. There is also the fact that, in Mr. Hutchinson's Clinical Lecture of April 1871 (*Lancet*, April 29th, 1876), a case is quoted, of which the notes were taken in December 1867. The portrait and the notes surely form more definite evidence than any statement by Mr. Tweedy or myself, founded on familiarity with the teaching of Dr. Fox and Mr. Hutchinson.

Then, again, as to comparing certain vesicles to grains of boiled sago, I had become so accustomed to hear Mr. Hutchinson use this strikingly apt illustration, that I failed to realise how much originality there was in it till I read Dr. Fox's communication to the *Lancet*. Though Dr. Fox is to be congratulated on having also been attracted by the resemblance, there is no doubt that sago grains had been made to do duty long before he wrote his paper. Had Mr. Tweedy even occasionally seen cases of diseases of the skin with Mr. Hutchinson, I have no doubt he would have made acquaintance with the views of the latter much sooner than 1873; but they had only been in the habit of meeting for a few months, and then ophthalmic subjects engaged attention almost exclusively.

Dr. Living's suggestion as to hyperidrosis seems to me worthy of consideration, for Dr. Fox's description of profuse discharge of acid fluid, in his last communication, certainly points to a different state of things from what I have found in real (or suspected) cheiro-pompholyx. Dr. Thin may place too much reliance on Dr. Robinson's negative observations; but, on the other hand, Mr. Tweedy has not proved the fluid he saw at the apertures of sweat-ducts to be other than serum. It is to be hoped that some patient who is not "nervous" will afford a believer in dysidrosis the opportunity of setting our minds at rest by demonstrative (positive) sections.

## REPORT OF FIFTH SERIES OF FIFTY CASES OF OVARIOTOMY.

By THOMAS KEITH, M.D.,

Surgeon for Ovarian Diseases to the Royal Infirmary, Edinburgh.

I HAVE again to record a diminishing mortality after ovariectomy. In the first series of fifty cases, there were 11 deaths; in the second, 8; in the third, 8; in the fourth, 6; in the fifth, 4. Of the four fatal cases, two died comatose, with suppression of urine, within thirty hours after operation; two died from blood-poison. One was a case of tumour of 53 lbs., complicated by a large fibroid uterus. I unwisely removed a pediculated portion of the fibroid, which seemed to be much in the way. A drainage-tube was put in behind the tumour in the pelvis. The tube was displaced, probably as the patient was moved into bed. No serum escaped by it; and a fatal result happened in a case that promised to do well. I have no hesitation in saying that earlier operation would have saved the other three, for they were originally healthy women. One was a large sarcoma of slow growth. When seen, the patient had been little out of bed for sixteen months. The tumour was removed quite easily; but extensive adhesions to the mesentery and intestine led to the tying of nearly a hundred vessels. In the third, also complicated by a large uterine tumour, an inflammatory affection of the knee prevented the patient from coming to town when she was prepared to do so six months before. During this time she was tapped six times, seven gallons of fluid being removed on each occasion. The cyst-walls alone weighed upwards of 50 lbs.; adhesions were universal, and of the utmost firmness, especially to the liver. The fourth fatal case—one of double dermoid cyst—had been often urged by Dr. Mackenzie of Larkhall to have the tumour removed in a favourable time. An injury caused rupture of the cyst, and for nine months she was confined to bed. For long she was blood-poisoned, and had double phlegmasia dolens, the œdema extending even into the axilla; yet she rallied after many tapings. The operation lasted three hours

and a half. Masses of fat and hair had escaped into the upper part of the abdomen, and had become encysted by thick deposits of lymph in a most wonderful way. All this had to be dissected out. When she was placed in bed after operation, the temperature had fallen to 92 deg.

Not included in the table is that of a case in which ovariectomy was performed a second time. The patient recovered. In two cases of acute suppurating dermoid cysts—one seen with Dr. Keiller, the other in Lanarkshire with Dr. Lindsay and Dr. Lennox of Hamilton—the pelvic adhesions were such that relief by ovariectomy could not be thought of; yet as both were in the last stage of the disease, it seemed right to try something. They were treated by incision and drainage, and both recovered perfectly. A third, similarly treated nearly two months ago, so far promises well in the hands of Dr. J. Cox of Innerleithen. Two cases of cyst of the broad ligament are apparently cured by tapping.

In three cases I was unable to complete the operation. One, aged 67, a patient of Dr. Lorraine, had been often tapped. On exposing the tumour, it was found to be malignant, with disease of the peritoneum. There was no ascites; the tumour was not disturbed. The second was sent by Dr. William Bell. Ascitic fluid surrounded a papillomatous growth. Early operation was advised, in the hope that no secondary affection of the peritoneum had yet taken place. The pelvis was filled with secondary growth, involving the base of the tumour, and I was unable to remove the pelvic portion. The third came from Dr. Borthwick of Dumfries. A large thin-walled cyst was so adherent that, though part of it was separated, the pelvic portion could not be removed. The cyst was fixed in the wound and drained. These three cases ultimately proved fatal.

As in former reports, every case is now given in which I have interfered with any abdominal tumour except by tapping. In the first hundred cases (*Lancet*, 1867 and 1870), deaths after incomplete operations were included amongst the deaths of the completed cases. A short history was also given of every case of ovarian tumour that was seen and not operated on, as well as the reason for not operating. A sort of balance-sheet was thus formed, by which the value of the oper-

Table of Fifty Cases of Ovariectomy.

No.	Medical Attendant.	Date.	Age.	Adhesions, Weight of Tumour, etc.	Result.
201	Dr. Dobie, Chester .. ..	June 1875 ..	52	Parietal, omental, and mesenteric adhesions; sarcoma; some ascites; 14 lbs. ..	Recovered
202	Dr. Bluny, Denny .. ..	June .. ..	43	Inflamed burst cyst; 20 lbs. ..	"
203	Dr. Greig, Dundee .. ..	July .. ..	23	Extensive parietal and omental adhesions; 40 lbs. ..	"
204	Dr. Dobie, Chester .. ..	September ..	49	Slight parietal and omental; 53 lbs.; pediculated uterine fibroid also removed ..	Died
205	Professor Lister .. ..	September ..	40	No adhesions; 25 lbs. ..	Recovered
206	Dr. Herring, Eulith, Brecon ..	September ..	68	General parietal adhesions; 47 lbs. ..	"
207	Dr. Ross, Inverness .. ..	October .. ..	48	Extensive parietal and omental adhesions; 17 lbs.; fibroid of uterus ..	"
208	Dr. Campbell, Dundee .. ..	November ..	55	Omental adhesions; 33 lbs. ..	"
209	Dr. Logie, Kirkwall .. ..	November ..	21	Semi-solid; 18 lbs. ..	"
210	Dr. Hay, Carlisle .. ..	January 1876 ..	35	Burst cyst; 17 lbs. ..	"

247	Dr. Johnston, Stirling .. ..	October .. ..	45	Parietal; 34 lbs. ..	"
248	Dr. De Vitre, Lancaster .. ..	October .. ..	53	Extensive adhesions to uterus, bladder, and pelvis; 27 lbs. ..	"
249	Dr. Cullen, Helensburgh .. ..	October .. ..	20	Omental adhesions; sarcoma; 7 lbs.; ascites; double pleurisy ..	"
250	Dr. Dickson, Carnoustie .. ..	November ..	27	Parietal and omental adhesions ..	"

ative results might be judged. In the second hundred cases, the London example was followed, and the deaths after completed and incomplete operations were separated; but details were given of every case of incomplete operation. Now, the practice seems to be to ignore altogether incomplete operations, exploratory incisions, or errors of diagnosis.

My confidence in the cautery in the treatment of the pedicle was some time ago shaken by hearing of a death from hæmorrhage the day after operation in a case where it was employed. In four-fifths of the cases in this series the clamp was used, the cautery being reserved for very short pedicles. Of late, my faith in the cautery has returned, and I have used it in some ordinary operations. The last twenty-one operations were performed under the carbolic acid spray.

Sulphuric ether has now been given in two hundred operations. Properly administered, it is nearly a perfect anæsthetic. I have pleasure in acknowledging the value of Mr. Ormsby's simple inhaler.

## JABORANDI PROPOSED AS A REMEDY IN HYDROPHOBIA, FROM OBSERVATIONS IN TWO CASES OF THE DISEASE IN MAN.

By J. G. SINCLAIR COGHILL, M.D., F.R.C.P. Edin.,  
Physician to the Royal National Hospital, Ventnor.

THE attention both of the public and of the profession is at present so much taken up with the subject of hydrophobia, that I have thought my experience of two cases of this disease, presenting some special features of interest in connection with its etiology, and perhaps suggesting a means of relief, if not of cure, might perhaps be of service in elucidating the natural history of this obscure disorder. During my residence in China, I had an opportunity of seeing the only two cases of hydrophobia which, so far as I have been able to ascertain, have ever occurred among the European residents in that empire. Rabies is by no means uncommon among the native dogs, but not so much so as one would expect from their neglected condition and cruel treatment. The cases to which I refer created great interest, I may almost say excitement, among the European community at the time, not only from the rarity of the affection, but also from the circumstances under which they were presented.

The first case occurred during the hottest part of the season of 1866. The sufferer was a young Englishman in robust health, tea-taster in one of the leading mercantile houses, who had recently arrived from England, and, like many of the new comers, had been attacked with an abundant crop of boils; some of these, in the neighbourhood of the ankles, had become somewhat ulcerated from rubbing. On the Sunday afternoon, he had been awakened from a nap by his little English bull-terrier licking one of the ulcerated spots on the ankle. The dog had been observed for some days previously to be somewhat cross and snappish, and much less playful than usual; but this was attributed to the oppressive heat of the Chinese summer, of which this was its first season's experience. Within fourteen hours, the unmistakably characteristic symptoms of the dreadful disease had manifested themselves, and within thirty-six hours proved fatal. Morphia, and then the sulphate of atropia, in heroic doses, were injected hypodermically without the slightest effect. Extract of belladonna was applied with the same result along the spine; but the only relief obtained, and that for brief intervals only, was by applying an improvised ice-bag to the back, and the inhalation of chloroform as continuously as the greatly embarrassed condition of the respiration would permit. The infecting dog was destroyed before any more active signs of rabies developed themselves.

The second case presented itself in the person of another young Englishman, an *employé* in the Imperial Customs at Shanghai. He was brought to the General Hospital two days after the death of the preceding, and had been greatly impressed by hearing of it. His attention was drawn to what had hitherto been an almost imperceptible scar on the ball of the thumb, which had resulted from the bite of an "angry" dog in England, nearly two years before. It had now become irritable and red, but did not actually open or ulcerate; but in this case also the same terrible symptoms developed themselves with an equally rapid and fatal result.

These two cases involved me in a somewhat lively correspondence with my friend Sir Edmund Hornby, the Chief Judge of the Supreme Court, who, without having seen them, wrote to the papers, saying he believed they were cases of a purely nervous character, terminating fatally from the intensity of the mental impression, and that he had seen many cases of the same kind

during his official residence in Constantinople. But of the true hydrophobic character of these two cases there could be no doubt whatever in the minds of all who saw them. Indeed, I for one do not know any disease of which the symptoms, in form and sequence, are more characteristic. The pathogeny of the disease in each of the cases in question was peculiar. In the first, the inoculation was effected by the saliva of a dog in whom the disease was not markedly developed, and then by absorption from the ulcerated surface. This did not prevent the disease from being at once developed, and running its course with extreme rapidity. In the second case, the original site of inoculation nearly two years before had completely healed, but the poison evidently remained latent in the system until the circumstance of a new case again directed the mind of the patient strongly to his own experience, with an intensity sufficient to rouse the slumbering mischief into fatal activity. It is impossible, I think, to overlook the mental impression as an important factor in the morbid process, where a sufficient predisposing etiological element exists in the potentially affected organism. The exciting cause need not be essential in character, and very often is here as elsewhere out of all proportion to the morbid action which it initiates.

Among the pathological lessons taught by the study of this disease, is to be noted the variety in the morbid species produced by transmission from the lower animals to man. The natural history of hydrophobia shows abundantly that, in the lower animal, very often the phenomena of the disorder are altogether less strikingly developed, and do not present that terrible intensity which agonises the human sufferer and appals the beholder. The dog may only appear dull and stupid and disinclined to play, perhaps a little cross and snappish with strangers, able to swallow both solids and fluids, as shown by voluntarily licking its master's sores, showing therefore none of the purely *hydrophobic* phenomena, and yet be capable of communicating the malady in its most acute form to man, in whom the hydrophobic character is so markedly pathognomonic.

I do not know that I would have thought these reminiscences of hydrophobia of sufficient interest to add them to the already teeming literature of the subject, except that, in recalling the individual symptoms, I remember one at least which suggests that, in a recent proposed addition to our *materia medica*, we may possibly have a means of relieving the most distressing symptoms of hydrophobia, if not of eliminating the poison itself and curing the disease. In the first of these cases, I particularly noticed that there seemed to be an entire suspension of the functions of the whole salivary apparatus. The tongue, mouth, and fauces were perfectly dry; and of this condition, and an intense sensation of thirst apparently associated with it, the patient chiefly complained as his greatest source of distress in the intervals of the tetanic spasm. Strong efforts only resulted in the collection of pieces of tough viscid mucus, which could not be swallowed, and which were ejected with frequent and difficult efforts. This is in striking, and, as I would point out, important contrast to the dog, where the saliva may be seen flowing abundantly from the open mouth. The specific animal as well as the mineral poisons, appear to have a special affinity for particular organic systems, as the vehicle or apparatus for their elimination from the body. Of these organic systems, the skin and the salivary glands seem to be by far the most active, and it is more than probable that their action is mutually vicarious. These facts are too well known to require any further illustration. Now, as the saliva is evidently the secretion in which the poison of rabies, in the dog at least, is found most abundant, and by which it is propagated, it follows that the salivary glands must be largely, if not specifically, involved in the morbid action. If we find, then, the whole salivary function suspended, or at least impeded, in cases of hydrophobia in the human subject, ought we not to accept the physiological indications so plainly presented, and endeavour to restore the action of the salivary glands as the special emunctories of the morbid poison. I think that this is the direction in which we are to look for our remedy; and I believe that it will probably be found in the *jaborandi* of Mexico, the latest transatlantic addition to our *materia medica*, and which has shown itself to be the most potent sialagogue and diaphoretic known. The only cures of hydrophobia (for such are reported on credible authority) have been in cases where either the morbid nervous phenomena have been reduced by their physiological antagonistic curare, while the *materies morbi* has been allowed to exhaust itself, or its elimination has been left to the natural efforts; or, on the other hand, where the excretory action of the skin and salivary glands have been excited by the hot-air or mercurial bath. Even admitting that such cases were not those of true hydrophobia, at least they are evidence that symptoms, markedly partaking of this grave character, have been at least relieved by rousing the action of the skin and salivary apparatus.

The dose of the powdered leaves of *jaborandi* is from sixty to eighty

grains; and, as no dangerous effects have attended the somewhat free experiments hitherto made with it in the healthy subject, it may be given with confidence. I would propose that an infusion of one drachm of the powder, in an ounce of water, be injected at a blood-heat into the rectum, and repeated every two hours until the full influence of the drug is established. If there be intolerance of the simple infusion, it may be medicated by the addition of liquor opii and starch, so as to facilitate its retention. If the active principle of the drug could be obtained, it would, of course, be much more easily managed in the form of a concentrated solution for hypodermic injection. The liquid jaborandi of Messrs. Ferris and Co. I have found to be a reliable test. The dose is from five to ten drops. It is therefore presented in a handy form for injection either *per rectum* or hypodermically.

## ON THE TREATMENT OF HIP-JOINT DISEASE BY EXTENSION WITH MOTION,

AS PRACTISED BY THE AMERICAN SURGEONS, INSTEAD OF LONG-CONTINUED REST AND IMMOBILITY.\*

By WILLIAM ADAMS, F.R.C.S.,

Surgeon to the Great Northern Hospital, and to the National Hospital for the Paralysed and Epileptic; Consulting Surgeon to the National Orthopaedic Hospital; etc.

THE object of the present paper is to direct attention to the recent advances which have been made in the treatment of hip-joint disease by the American surgeons, to whom we are indebted for the discovery of two very important principles, and also for their practical application by means of most ingeniously contrived instruments.

The first principle is that of extension, as a means of relieving the most acute pain in joint-diseases, especially applicable to the knee and hip-joints.

The second principle is that of extension combined with motion during the progress of disease, the patient being allowed to walk about, so as to promote recovery with free motion in the joint, instead of the ordinary result of ankylosis obtained by long-continued rest and immobility.

There can be no doubt that the discovery and practical application of these two principles have completely revolutionised the treatment of joint-diseases, and changed our opinion with regard to the pathological conditions existing, especially as to the production of acute pain which, formerly, was believed to depend upon acute inflammation, requiring active local, as well as general antiphlogistic treatment, such as leeches, blisters, calomel and opium, etc. It has now been proved to depend upon undue articular pressure and contact of inflamed surfaces, produced by reflex muscular contraction, and capable of relief by mechanical means alone, producing extension, whether this be applied by means of the weight and pulley, or by the screw and cog-wheel.

The object of extension is not, as generally supposed, to separate articular surfaces, but to overcome reflex muscular contraction, and, by relaxing the muscular rigidity, to prevent undue pressure of inflamed articular surfaces, or their margins, when the joint is held in a flexed position by muscular contraction.

Extension, for the relief of pain, is applied by means of the weight-and-pulley apparatus whilst the patient is in bed, the extension always being made in the same direction as the long axis of the limb. It will vary, therefore, when first applied, as the leg may be flexed, adducted, or abducted; but as soon as the reflex muscular action has been overcome, the weight will be made to pull in the direct horizontal line. After the pain has subsided, the object with which the weight-extension is continued is to secure sufficient rest to the joint, and at the same time permit a limited amount of motion, as the patient varies his position in bed. It is not found, by experience, that the limited amount of motion thus permitted in any way interferes with, or retards, the favourable progress of the case; but, on the contrary, this may be looked forward to with confidence in the great majority of cases after the pain has been relieved by the weight extension. The health of the patient also improves rapidly after the relief of pain.

The successful application of weight-extension as a remedy for pain, however acute it may be, in joint-disease, is the greatest discovery of modern times in the treatment of these affections. The originality of this discovery is claimed by Dr. Henry G. Davis of New York. In his work on *Conservative Surgery*, published in the year 1867, at

page 206, Dr. Davis observes: "We consider it fully established that, when disease about a joint renders the movement of that joint painful, the joint is always liable to be destroyed by uninterrupted pressure effected through the contraction of the muscles passing over it." And again at page 212, "In diseases of joints, we were the first to point out, as an always present factor in their destruction, the existence of unremitting pressure, as effected by contraction of muscles passing over the joints, causing constant forcible apposition of the surfaces within the joint. This is a general principle appertaining not only to the hip, but to all joints similarly affected. The application of this universal principle should guide us in any joint-affection, whether the disease be internal or external, as soon as the disease renders the movements of the joint painful. When this fact was fully established in our mind, we were led to seek the best way of counteracting the contraction of the muscles, and soon came to the conclusion that a constantly acting force, however moderate, must eventually weary muscles by giving them no respite. We adopted the weight as applied by means of the cord, pulley, and adhesive strips for this purpose, when the patient was confined to his bed or couch. This answered the indication perfectly, relieving all pain and constitutional disturbance, enabling the patient to enjoy his days free from pain, and to rest quietly at night, to relish his food, and to be nourished by it; in short, it robbed the disease of all its terrors".

Dr. Davis does not precisely state the period at which he arrived at the above conclusion as to the cause of the acute pain and its method of treatment; but it must have been anterior to the year 1855, which is the date affixed to his extension splint by the instrument-makers Otto and Reynders of New York. At page 308 he states: "In 1856, I had fully established the treatment of morbus coxarius upon the plan of overcoming the pressure effected by the muscles, through the means of *continued elastic extension*, and the mode with its results was very flatteringly commented upon by one of the editors of the *American Medical Monthly* of this city, in March 1857."

There can be no doubt that interarticular pressure, or the pressure of inflamed articular surfaces—one surface being generally pressed against the margin of the opposite articular surface—must take place when the joint is drawn into a flexed position by the rigid contraction of the muscles, more or less of a spasmodic character, which always coexists with the period of acute pain. Mr. Hilton has particularly pointed out this fact in his *Lectures on Rest and Pain*, and has explained it to be the result of reflex nervous irritation, depending upon the anatomical fact of the various muscles surrounding the joint being supplied by branches of the same nerves, which are also distributed to the interior of the joint. The explanation of this period of acute pain in joint-disease, and its dependence upon interarticular pressure, produced by the abnormal contraction of the muscles surrounding the articulation, has been brought before the profession in a very able paper by Mr. Howard Marsh, in the *St. Bartholomew's Hospital Reports*.<sup>†</sup>

The English idea has always been rest and immobility to the joint. The American idea, during the last ten years, has been extension with motion, *i.e.*, preserving motion in the joint whilst the pain is relieved by extension.

In the treatment according to the English system, immobility of the joint is obtained by various instruments and splints; from that piece of surgical antiquity, the *long straight splint*, reaching from the axilla to the foot, necessitating the confinement of the patient in the horizontal position for many months, and many other contrivances, such as metal and leather splints to the joint, which permit the patient to move about on crutches, to the now somewhat fashionable Thomas's splint, invented by Mr. Thomas of Liverpool, and described in his recently published work.

All these means succeed, more or less, in relieving pain and promoting recovery, although ankylosis is frequently produced, and this has generally been regarded as the most desirable termination; but in many cases they all fail in relieving pain, for want of the American extension principle, and also they do not prevent the occurrence of dislocation, or partial dislocation, the effect of which is to produce shortening of the limb with permanent lameness.

An example of this occurred recently in my own practice, dislocation, or partial dislocation, taking place whilst the patient was wearing a Thomas's splint. A young gentleman, aged 6, was brought to me in March of the present year, suffering from slight symptoms of hip-joint disease; no pain, but limping, with muscular rigidity, and and slight flexion of the hip-joint. I ordered Thomas's splint, which

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

† On the Prejudicial Effect of Interarticular Pressure in Joint-Disease; and the Application of Continuous Extension by means of a Weight, as a Remedy for this Condition. By F. H. Marsh.—*St. Bartholomew's Hospital Reports*, vol. ii. London: Longmans, Green, and Co.

was made by Mr. Krohne, and applied by myself, with his assistance. I also ordered an extension-apparatus to be used at the same time with Thomas's splint, as the absence of extension appeared to me to be its chief defect. The splint, however, appeared to answer its purpose so well, and the child could be so readily moved about and taken into the open air, and at the same time apparently improving, that the extension-apparatus was not used by the parents, and I saw no more of the patient until sent for in consequence of the occurrence of pain, chiefly at night. This took place nine weeks after the application of Thomas's splint, and it continued two or three weeks before I was sent for; and I then discovered that a dislocation, or partial dislocation, of the head of the femur had taken place; shortening of the limb was apparent, the top of the great trochanter being nearly on a level with the anterior superior spinous process of the ilium. After this the pain ceased, and the disease will probably be arrested; but there must remain permanent shortening, with lameness, and probably complete loss of motion. I am, however, now trying persistent extension night and day, in the hope of diminishing these evils, which could not have occurred if the American system of extension had been relied upon, or extension combined with Thomas's splint, which I ordered. On July 17th, Professor Sayre went with me to see this patient, as he was desirous of seeing cases in which Thomas's splint had been applied.

In my own practice, during the last ten years, since the publication of Dr. Davis's book, I have, in the treatment of hip-joint disease, relied chiefly upon weight-extension, at the commencement, continued day and night with the patient in bed, especially if pain exist; but, as improvement takes place, I allow the patient to walk about with the assistance of crutches, wearing at the same time a firm leather splint moulded to the hip, reaching from the waist to the knee. This secures rest and immobility to the joint, whilst general exercise of the body is permitted; but during the daytime, whilst the patient is not walking about, the leather splint is removed, and the weight-extension applied whilst the patient is on the sofa. Immobility, therefore, is not long continued; and in all cases where the disease has been arrested in the early stage, after treatment lasting from one to two years, motion at the hip-joint has always been preserved, and no lameness whatever remains. Patients treated in this way some years ago are now able to walk and take horse exercise without any fear of the recurrence of pain or any inconvenience.

When disease has not been arrested in the first stage, but has advanced to abscess, with destruction of the joint, motion is generally lost, and ankylosis results; but in some cases, in which I have relied upon extension throughout the disease, an useful though limited amount of motion has resulted.

Before concluding this paper, I will allude to the second principle in the treatment of hip-joint disease, for which we are indebted to the American surgeons—viz., that of extension combined with motion, allowing the patient to walk about during the progress of disease, so as to promote recovery with free motion in the joint, instead of the ordinary result of ankylosis obtained by long continued rest and immobility.

The most recent American advance has been to combine extension with the preservation of motion, and at the same time to allow the patient to walk about without crutches, the weight of the body being transmitted to the ground by a steel instrument applied to the limb from the waist to the foot, or rather a little below the foot. Attached to the steel band round the waist, are two firm inelastic perineal bands, which, passing from before backwards below the tuberosity of the ischium on each side, receive the weight of the body. A raised boot of one inch in thickness is worn on the foot of the sound limb. The limb is connected with the foot-piece of the instrument by means of two long strips of plaster, extending from a little above the ankle to the middle of the thigh, and retained in position by a circular bandage. Attached to the lower extremity of each strip of plaster is a buckle, to which is fastened a strap coming upwards from the foot-piece of the instrument. When thus connected, extension is made by means of a rack and pinion in the longitudinal bar of the instrument at about the middle of the calf. Inversion and eversion of the foot can also be controlled by a circular cog-wheel placed a little below the hip-joint.

The instruments now generally in use in America for the application of extension with motion, whilst the patient is allowed to walk without crutches, are those invented by Dr. Taylor and Professor Sayre of New York, also one by Dr. J. C. Hutchinson of Brooklyn, all of which are modifications of the instrument first invented for this purpose in the year 1855 by Dr. Henry Davis of New York.

My own experience in the use of these instruments is very limited; but, during my visit to America last year, I had the opportunity of seeing them applied in a large number of cases, and as it appeared to me

with great advantage. In one case, that of a young lady, who was residing in Dr. Taylor's private establishment in New York, where patients are received for the treatment of various deformities, the hip-joint disease appeared to be in a more active stage, judging from the pain she suffered, than I should have thought the walking instrument could have been applicable; still, when the extending force was applied pretty nearly to its full extent by Dr. Taylor, she was enabled to walk without pain, and therefore it seemed to be a test-case of the value of extension. Children with hip-joint disease in a more chronic form are frequently seen walking about the streets of New York wearing these supports, and are enabled to get in and out the tramway-cars without difficulty.

Dr. Sayre applied his walking instruments (represented in fig. 2), made by Ernslof London, a fortnight ago, to one of my cases, a young gentleman six years of age, from Ireland, and he was enabled to walk about with ease and comfort; but, as he was previously free from pain, the case was less a test of the value of extension than that previously alluded to.

These instruments and their mode of application are described by Dr. Sayre in his *Lectures on Orthopaedic Surgery*, published in 1876; and, as we have now the pleasure of welcoming Dr. Sayre amongst the distinguished guests present at this meeting of our Association, I am glad to state that he will exhibit the hip-joint instrument of his own construction, with the latest improvements, and make some observations on its application.

The accompanying woodcuts, which were kindly forwarded to me by Dr. L. Sayre of New York, for the purpose of illustrating this

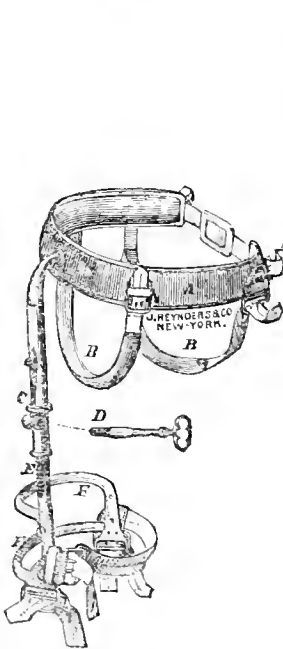

Fig. 1.—Dr. Sayre's short Hip-Joint Splint.

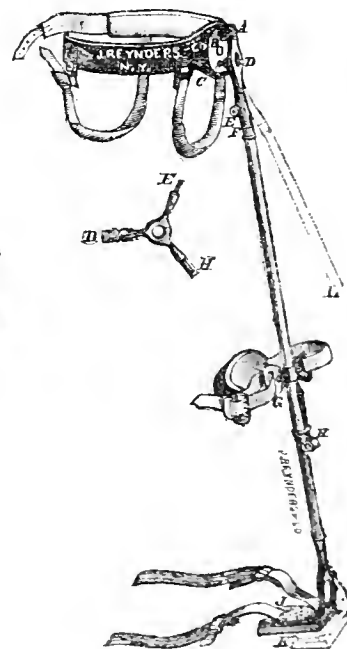

Fig. 2.—Dr. Sayre's long Hip-Joint Splint.

paper, represent the two hip-joint instruments used by him for combining extension with motion in the treatment of hip-joint disease. Both these instruments are figured and their application described in Dr. Sayre's recently published *Lectures on Orthopaedic Surgery*, pp. 262 and 269.

ALCESTER.—A considerable portion of the report for the quarter ending September 30th was taken up with the details of the action taken for the prevention of the spread of scarlatina and typhoid. As regards the former, he regrets not having a disinfecting chamber, and relates a successful prosecution for the exposure of some children while in an infected state. As regards the latter—typhoid—Mr. Fosbroke relates the history of two outbreaks in some isolated cottages, which occurred at first from polluted water-supply arising from defective drains, and afterwards from the excreta of the infected having been thrown into the common privy without disinfection. The annual death-rate was only 14.9 per 1,000 living.

## CLINICAL MEMORANDA.

## PYLORIC DISEASE.

DR. SUTTON's success in his cases of pyloric disease, treated by withholding food, and reported in the JOURNAL for December 8th, is confirmed by a case that occurred in my private practice many years ago. A lady of middle age, with great strength of character, was the subject of scirrhus of the pylorus, attended with distressing pain and vomiting after taking food. As the disease was rapidly advancing, I consented, at her own request, to abstain from giving food by the mouth, with the exception of a few teaspoonfuls of milk that were swallowed in the twenty-four hours to satisfy the natural craving of the stomach. She was fed, during the last three months of her life, by the injection of animal broths; and the gastric pain was in great measure subdued by opiate enemata. This patient was contented with the method of sustaining life she had herself suggested; and as I watched the case from day to day, I could not help being convinced that she had been spared much of the usual suffering, under such circumstances, by the negative treatment adopted. The *post mortem* examination showed the existence of a large areolar cancerous ulcer, occupying a circular space of six inches in diameter and including the pyloric orifice. The margin of the ulceration was hard and thickened, and the surface exhibited the characteristic submucous degeneration of advanced malignant metamorphosis. There were but few altered blood-particles, and, consequently, but little of the usual coffee-ground appearance in the stomach.

HENRY DAYMAN, F.R.C.S., Millbrook, Southampton.

## PROLAPSE OF THE INTESTINES.

IN reference to Dr. Joy's case of prolapse of the caecum, reported in the JOURNAL of December 15th, 1877, I may state that a case very similar occurred at St. Bartholomew's Hospital in the autumn of 1860 or 1861, and was reported by me in one of the medical journals. The patient was a child about two years old, admitted under the care of the late Dr. Edwards, but died in a few hours, before any notes could be taken of the case.

At the *post mortem* examination, the whole of the large bowel was found to be invaginated within itself, the caecum being quite protruded, the ileum opening without the anus. After some research, I discovered some notice of such cases in a French pathological work; but the reference has been mislaid, and I cannot remember the name of the author.

THOMAS FAIRBANK, M.D., Windsor.

CASE OF VILLOUS DISEASE OF THE BLADDER :  
CATHETERISM : ABORTIVE ATTACK OF  
URETHRAL FEVER OR SEPTICÆMIA.

MR. T. D. C., aged 62, a total abstainer, has had for the last two years irregular fits of hæmaturia, accompanied with a frequent desire to micturate and more or less pain. On July 23rd, he came to me complaining of inability to pass urine, severe pain at the neck of the bladder, and frequent straining; he had for several days been voiding large quantities of bloody urine. I had no difficulty in passing a No. 9 catheter, and drew off about two pints of urine largely mixed with blood. I prescribed complete rest and ten-grain doses of gallic acid, with tincture of digitalis, every four hours. On July 24th, he had passed a better night than he had done for a long time, but was still unable to pass more than a few drops of urine. I again introduced a catheter with the same result as before. On July 25th, my friend Mr. W. H. Rix saw the case with me; and we decided to tie a catheter in the bladder, thinking that, if any of the hæmorrhage came from the prostate, which was somewhat enlarged, it might help to check it, and would also avoid the necessity of straining. The catheter was provided with a plug, and the patient could empty his bladder as often as required. The blood in the urine was not diminished. On the morning of July 27th, the patient told me he felt very comfortable and had passed a good night. I changed the catheter, and all appeared to be going on well until about 6 P.M., when I was hastily summoned and found him suffering from a severe rigor, which had lasted for nearly an hour, and talking incoherently. The catheter had been withdrawn. The temperature, which that morning had been normal, had now risen to 105.6 deg. His skin was very dry. I learnt that about midday he had been to stool, and in straining had apparently somewhat squeezed out the catheter from its position. On returning to bed, he had felt what seemed to be the point of the instrument, the pressure of which caused intense pain. I saw him again that evening at 9.30. The tempera-

ture had fallen to 102.5 deg. and the skin was acting profusely. Next morning, the temperature was normal, and has remained so since. I passed the catheter daily for about a week afterwards, and since then he has been able to empty his bladder fairly and the blood has almost disappeared. There can be no doubt, from the history of the patient, that the case is one of villous disease of the bladder, to which the hæmaturia is due. The feature of interest, however, in the case is the occurrence of the rigor on July 27th, following a misplacement of the catheter, which he had worn without hindrance for four days. To what may that rigor be referred? It was of extreme severity, as evidenced by the sudden and alarming rise in temperature and the equally sudden fall. That it was not the precursor of any febrile symptoms puts the view, I think, of its being due to septic absorption from the seat of disease out of the question. It would rather be compared to examples of so-called "urethral fever", following slight laceration or injury to the urethra during catheterism; or occurring even simply from the mere passage of a catheter in a subject not previously accustomed to the operation. If it be of this nature, the remarkable severity of the transient pyrexial state is worthy of note.

## SURGICAL MEMORANDA.

## FOREIGN BODIES IN THE EAR.

IN further confirmation of the well-known principle referred to by Mr. Dalby, in the BRITISH MEDICAL JOURNAL of December 15th—viz., that a foreign body in the external meatus, if "left alone, cannot do harm"—the following case is interesting.

E. R., a professional gentleman, aged 41, came to me on September 21st, 1877, complaining of deafness in the right ear that had come on during the last fortnight. He attributed it to a violent catarrh, accompanied by a sore throat, that had troubled him considerably of late. On examination, his tonsils proved to be slightly enlarged; the pillars of the fauces, uvula, and soft palate relaxed. The ear-speculum revealed the presence of a dark-looking body, resembling wax, that appeared to half fill the right meatus. Appropriate remedies relieved the catarrh and throat trouble, but the deafness remained. A few days later, the right ear was thoroughly syringed with tepid soap and water, when, to our astonishment, in addition to an abnormal quantity of wax, a foreign body was removed, which proved to be about a quarter of an inch of the cedar shaft of a penholder. On examining the meatus after removal, it presented no abnormality. The patient remembered distinctly the fact of its introduction, when he was a boy at school, quite thirty years ago. No attempt had ever been made to extract it, and its presence had not troubled him until now. His deafness entirely left him within a few hours of its removal.

H. HABGOOD, M.R.C.S., Eastbourne.

ANEURISM OF THE ANTERIOR TIBIAL ARTERY,  
TREATED BY COMPRESSION.

MR. T. came under observation on July 12th, 1877. He had suffered from rheumatism (?) since November 1876. He was spanæmic, extremely feeble, much emaciated, and complained of pain in the right ankle and up the leg, which was slightly larger than its fellow, but neither inflamed nor oedematous. He had walked up about thirty stone steps with difficulty on the previous day. He had a loud mitral murmur, which had probably existed for many years (after scarlatina), as Dr. Walshe, fourteen years ago, enjoined abstinence from the ordinary sports of boyhood. I ordered belladonna liniment to the feet, and syrup of iodide of iron, and ceased attendance, as he improved, after four days.

On July 30th, I again visited him. There was much pain in the right leg below the knee externally, and down the outside of the leg. I ordered a warm lotion of iodide of potassium; and two days afterwards, for the first time, I discovered a distinct pulsating swelling between the tibia and fibula, at the upper part of the leg. There was no discoloration. The tumour could be emptied on pressure, and the pulsation controlled by compression of the popliteal artery. It seemed to be nearly as large as a small hen's egg. A to-and-fro murmur was audible with the stethoscope. Ten grains of iodide of potassium were ordered every four hours, and, after consultation with Mr. Bickersteth on August 3rd, a trial of compression was determined on, although it was agreed that the patient was a most unfavourable subject for such treatment, for the ligature, or any surgical procedure. I fortunately obtained the aid of Mr. Jones, House-Surgeon to the Liverpool Royal

Infirmity; and on August 4th, at 11.30 A.M., two tourniquets were applied to the limb, with intervening pads of cotton-wool: one (Signoroni) over Poupard's ligament; the other (Liston) a little above the middle of the thigh. These respectively controlled the common and the superficial femoral, and were every hour tightened and relaxed. A quarter of a grain of morphia was injected hypodermically at the commencement of the compression, and again at 3 P.M., and the patient exhibited scarcely any manifestation of pain. The tourniquets were removed at 6.30 P.M. (*i. e.*, after seven hours), when the tumour was found to be consolidated. The tissues were red over the seats of pressure, and the leg was a little swollen. Its temperature, to the hand, appeared to be higher than that of the opposite limb. The patient remained in a very lethargic state; and, at 11 P.M., catheterism was performed, as he had not passed any urine during the day. The next morning, the tumour was free from pulsation; there was not any discoloration; and the leg was nearly of the size of its fellow. He had slept much, but taken very little food beyond half a cup of turtle-soup. He was rather incoherent, but this had been noticed before the treatment. He spoke a little the next day, but never left his bed, or thoroughly regained consciousness until his death on August 25th. There was also an aneurism of the facial artery, larger than a cherry, below the jaw, on the same side of the body, and a very small one of the temporal, in front of the meatus of the ear; and the cerebral symptoms under which he sank were consistent with the suspicion that the intracranial arteries were similarly involved. According to Lisfranc, quoted by Druitt, out of one hundred and seventy-nine cases of spontaneous aneurism, exclusive of the aorta, there were three of the anterior tibial and two of the temporal. The facial is not mentioned, not having been affected.

The above case is interesting from its relative infrequency, and the existence of what may be termed an aneurismal diathesis; also from the favourable result, as far as the aneurism was concerned, in a very unpromising subject with cardiac mischief; from the tolerance of the pressure, and absence of subsequent local inflammation, irritation, or cedematous enlargement.

W. BOYD MUSHET, M.B.Lond., M.R.C.P.Lond.

#### ST. MARY'S HOSPITAL.

##### DR. BROADBENT'S WARDS.

*Cases of Mitral Stenosis.*—A boy had, from some cause not apparent, acquired a distorted condition of the spine, and, as a secondary result, the capacity of his chest was much diminished, so that, when admitted to the hospital suffering from bronchitis, his respiration was very embarrassed. At this time, a well marked tricuspid murmur was heard, the regurgitation apparently depending upon the impeded pulmonary circulation; this tricuspid murmur has now given place to a presystolic *bruit* at the apex. Dr. Broadbent remarked that the case is now in a very instructive stage of the disease; there is a loud and sharp first sound heard at the apex, while the *second sound* is not heard at the apex at all, so that, if the second sound be traced downwards from the second right cartilage towards the apex-beat, it is rapidly extinguished on passing from the right to the left ventricle; at the same time, the pulmonary second sound, as heard at the second left cartilage, is accentuated, owing to the impeded pulmonary circulation. This condition of the second sound is very characteristic of mitral stenosis.

In the case of a woman with a presystolic *bruit* at the apex, the murmur occupied almost the whole of the diastolic period, the apex thrill being of the same duration. The case appeared to afford strong evidence of the view that the presystolic *bruit* is due to the auricular systole, as opposed to the view that the sound is due to the imperfect closing of the stiffened margins of the mitral curtains at the beginning of the ventricular systole, an act necessarily of short duration; while we can readily conceive that the auricular systole may be easily prolonged, as it probably is in this case.

After a careful examination of many cases of heart-disease, Dr. Broadbent has never seen auricular pulsation at the surface of the chest, such as has been described by other authors.

*Disease of the Aortic Valves.*—An old man presented the signs of extensive dilatation and hypertrophy of the ventricles, accompanied by a loud double aortic murmur. The chest heaved with the impulse of the

heart, and the right ventricle was seen beating in the epigastrium; the apex-beat was displaced outwards and downwards. At a point just below the left nipple, the cardiac impulse produced a systolic and diastolic blow against the chest-wall, while only a systolic impulse was seen at the apex-beat. This phenomenon appeared to be due to the great amount of cardiac hypertrophy; at each of the points the systole produced a blow against the chest-walls, and at the higher point the thickening of the hypertrophied ventricle caused also a diastolic impulse, which was not produced at the apex. The dilated aorta produced a visible systolic impulse to the right of the upper part of the sternum. It appeared impossible to say whether the aorta was simply dilated or whether there was a small aneurism; but Dr. Broadbent did not think aneurism was present, as there was neither extended area of dulness nor any sign of pressure.

*Salicylic Acid in Acute Rheumatism.*—Dr. Broadbent has used salicylic acid largely in the treatment of acute rheumatism. He usually orders twenty-grain doses of the acid, dissolved by means of carbonate of soda, to be given every hour, to six doses, on two successive days. This drug has been found exceedingly useful, not only in lessening the pain and lowering the temperature, which it undoubtedly does, but also in preventing endocarditis and other complications.

Relapses have occurred in many of these cases, but only when the salicylic acid has been omitted too early. The drug also appears distinctly to encourage sweating.

*Pleuritic Effusion.*—A woman was admitted with the following physical signs: extensive dullness over the lower part of the right chest, extending much higher posteriorly than at the side or front, and bronchial breathing posteriorly, which rapidly extended; there was no elevation of temperature. The case appeared to be one of consolidation of the lung, when suddenly the physical signs of pleuritic effusion manifested themselves: the heart was slightly displaced to the left, the bronchial breathing disappeared at the base, and the whole of the right chest became very dull, although the vocal vibration remained well marked. Probably the lung had previously been extremely congested, and this condition was relieved when effusion occurred into the pleura. At present, tubular breathing is heard in the axilla and above the spine of the scapula; vocal vibration is diminished but not altogether absent below this line, while it is exaggerated above it; there is well marked *egophony* over a considerable area below the angle of the scapula, and distinct *bronchophony* above. Probably there is a moderate amount of effusion into the pleura, with either adhesions of the lung, or, as is more probable, a certain degree of congestion remaining, which causes the lung to be deeply immersed in the fluid, instead of being pressed upwards by the effusion.

*Temporary Hemiplegia.*—A middle-aged man was admitted on account of a recent slight attack of right hemiplegia. For several months previous to the present illness, he had been totally unable to work on account of chronic gout, from which he had suffered on and off for many years. It is noteworthy that, when attacked with hemiplegia, his speech became "stuttering"; a very unusual concomitant. This and the paralysis have now completely passed away. He suffers much from his heart, the least exertion or excitement causing faintness and distress. No cardiac impulse is seen or felt; and the first and second sounds, as heard at the apex, are alike in character and almost equidistant, resembling the sound "tick-tack". There appears to be dilatation of the ventricles, and probably some fatty degeneration. There is no albuminuria.

The temporary paralysis was attributed to cerebral congestion, dependent upon the gouty condition and the state of the heart.

#### EAST LONDON HOSPITAL FOR CHILDREN.

##### CASES OF SAYRE'S METHOD OF TREATING SPINAL CURVATURE.

(Under the care of Mr. ROBERT WILLIAM PARKER.)

CASE 1.—A. J., aged 3, an only child, pale and weakly, would be best described as a "backward child". There was a history of phthisis on the mother's side. In September, when first brought to the hospital, the mother said that, during the past month, the child had winced and seemed uncomfortable when walking about, but had not complained of pain; he also had a slight attack of jaundice, with symptoms of catarrh. On examining the back, a slight projection of the lower dorsal spines was recognised; there was, however, little or no tenderness on pressure. In reply to direct questions, the mother stated that the child was fretful and cross, and that he was steadily getting worse: the walking had gradually become more and more laboured and irksome, so that now he could hardly stand. There could be but little doubt that the case was one of early caries of the dorsal vertebrae. On September 6th, the child was suspended in a Sayre's tripod, and a

plaster of Paris jacket was applied, according to the instructions given by Sayre. For a few days afterwards, the child was kept in bed, in order to give the jacket time to dry. No marked alteration or improvement was observed in his general condition. At the end of a week, however, he began to recover his spirits and became more lively, and, by the end of the second week, he seemed to be much better, *i.e.*, he was less fractious, and seemed to walk about without much trouble. An interval of six weeks elapsed before he was again seen. The mother then gave the following account. "After the first fortnight or three weeks, the child began to droop again, and he soon became nearly as bad as before the jacket was applied. One morning, just a month after the plaster of Paris had been put on, the boy came out 'full of measles', and this completely took him off his feet. He went through a rather severe attack of measles, from which, however, he recovered." When seen (on November 16th), the jacket was, of course, at once removed. The prominent dorsal spines were a little reddened; but there were no other signs of friction and no signs of pressure. The lungs seemed normal. The boy was sent home, and the mother was ordered to well wash him and bring him back in a day or two to be again "jacketed". This was done accordingly. When the boy was brought for his second jacket, the mother spontaneously remarked that "he seemed to miss his support very much, and that he could not walk at all unless supported either by a hand or a chair". Three weeks after the application of the second jacket, the following note was taken. "The boy is much better in all respects; he walks about without any support."

CASE II.—A. R., aged 3½, first came under observation in November 1876 for spinal disease. There was no projection of the vertebrae, but there was tenderness over the spine, and progressive loss of power in the legs was coming on. The disease was situated in the lower cervical and high dorsal vertebrae. In August 1877, there was complete loss of power in the lower extremities. The diseased vertebrae now projected considerably. A Sayre's jacket was applied: not quite as Sayre recommends for cervical disease, for the head was not suspended in the "jury-mast", which is, no doubt, an essential part of the treatment of disease in this region. When, therefore, a week later, the child was brought to be looked at, it was not thought strange to have to record "he is not much better for the jacket". Nevertheless, after having worn the jacket for a month, the following note was made. "He can only just support himself; he is, however, much improved in his general health." His mother added: "He can kick his left leg now anywhere, and his right one is beginning to come to life again." This improvement is continuing steadily.

CASE III.—W. W., aged 3, twelve months ago first commenced to "grow out". He was found to have disease in the high dorsal vertebrae. There was a considerable curve in this region, which suggested disease in several vertebrae. It was supposed to have been caused by a fall which he had sustained three months previously to the "growing out". His legs dangled uselessly; he could not perform any voluntary movements whatever, and, as he lay in bed, if he wanted to move his legs, he had to do so with his hands. He had been "off his legs" for upwards of twelve months. The boy's general health was of a low scrofulous type; he was pale and flabby. A plaster of Paris jacket was applied in the usual manner. A fortnight later, the following note was taken. "He cannot yet stand, even with the aid of a chair; but he can flex his thigh and leg, *i.e.*, he can draw them up when he is on his back without the aid of his hands." A fortnight later, again, this note was made: "He can barely support himself on his legs, even with the aid of a chair." The boy can now walk without any support. He has worn his jacket six weeks in all.

REMARKS.—The foregoing cases illustrate various stages of spinal disease as seen in the out-patient department of a children's hospital. Other cases might have been added in which the same satisfactory results were obtained. Case II had been under observation for many months; he had taken cod-liver oil and various other tonics, and had been kept in bed. When first seen, there was no projection of the vertebrae whatever; there can be no doubt that, if he had been "jacketed" at first, the disease might have been arrested. When treatment as out-patient had failed, he was admitted into a hospital; but not only was there no improvement, the disease even progressed. In the other cases, there was more or less paraplegia; but, nevertheless, the extension effected by suspension and the support afforded by the plaster jacket together seemed to remove the pressure, which probably caused the paraplegia. Recovery took place because no very permanent secondary changes (as the result of this "slow compression") had taken place.

Mr. Parker is of opinion that the most satisfactory result will be obtained by treating cases which are progressing, but which are still in a comparatively early stage. If adhesions and consolidation have

taken place, extension ought to be practised with great care. Considerable art is required to adapt the jacket so as not to compress the chest too much, on the one hand, and for it not to be too loose, on the other. For, if the jacket be too tight, pressure-sores on prominent bony projections will result in spite of wool-pads; while, if it be too loose, friction-sores will be found. The latter are more likely to occur, and, with a view to obviate this as much as possible, Mr. Parker now advises, in all cases, that the spines of the vertebrae, and even the angles of the ribs, be covered with a good and unirritating adhesive plaster on wash-leather. This thoroughly protects the chest, and is far more efficacious than any amount of wool. More serious consequences than sores are said to have followed a too tightly fitting jacket; but such accidents will probably be as rare as gangrene of a limb after tight bandaging, and, like this, will not occur in the hands of a skilful surgeon.

#### BRADFORD INFIRMARY.

TUBERCULAR PHTHISIS: RIGHT HEMIPLEGIA, WITH EMPHYSMA OF LEFT MIDDLE CEREBRAL ARTERY.

(Under the care of Dr. ALEXANDER.)

JOHN McM., aged 30, a tailor, was admitted into the Infirmary on April 6th, 1875. He stated that five weeks ago he was in his usual good health, but that a month since he began to complain of cough, tightness across the chest, loss of appetite; and with these symptoms he remained in bed, growing daily weaker, until the day before admission, when he got up, dressed, and went down stairs. Upon the following day, it was discovered that he was paralysed; and it was believed that the hemiplegia had followed a severe fit of coughing. He had a pale emaciated appearance, and was very weak. There was absolute loss of sensation and motion in the right arm, and loss of motion, but not complete loss of sensation, in the right leg. There was partial paralysis of the right side of the face; and, on pinching the leg, he contorted the left side of his face; the left angle of the mouth being strongly drawn, and the left ala nasi notably raised, whilst the right half remained unaffected. The tongue was dry, red in the centre, slightly fissured, and, when protruded, turned to the right. The pupils were equal and dilated. There was no ptosis. He could close both his eyes, and the right half of the occipito-frontalis muscle was in action. Articulation was in a great measure abolished; he could say "No" pretty distinctly, but could not say "Yes" clearly. There was difficulty in swallowing, and slight deafness. Over the right lung, upon percussion, there was a flat dull sound at the apex both anteriorly and posteriorly, with prolonged wheezy expiration and suspicion of moist râles. Over the left lung, there was dulness, which diminished from above downwards. At the apex, the breathing was tubular; and near the nipple there was a whistling sound accompanying inspiration. Behind the left lung, there was dulness over the whole surface. The patient had a cough, but no expectoration. The heart-sounds, though faint, seemed normal.

April 7th. The patient was restless and exhausted. He attempted to get out of bed, and seemed to be sinking.

April 8th. He was better and stronger this morning, and more rational. Temperature 101; pulse 100, feeble; respirations 37 per minute. The tongue was moist, loaded with white fur. The urine was acid, of specific gravity 1028; no deposit or albumen. At ten o'clock, he became violent, began to suffer from hallucinations, and to cry out. The right arm and leg were both moved. I injected one-sixth of a grain of morphia. As he was no quieter, in fifteen minutes, another sixth of a grain of morphia was injected; and, he being no quieter in thirty minutes after this, ten grains of chloral-hydrate were given, which produced sleep in fifteen minutes. The respirations were reduced to 20 per minute.

April 9th. He had eight hours' sleep, and remained quiet all day. Respirations 30 per minute.

April 10th. He could swallow much better, and had a little feeling in the right arm and leg. He could draw up the right leg slightly.

April 15th. Crepitation was heard over the whole of the left lung and lower two-thirds of the right lung. He was a little better.

April 19th. His pulse was very weak, but he took his food well. The urine and feces had passed involuntarily ever since admission. He was rapidly losing flesh. The paralysis was no better. Bed-sores were forming.

The patient became gradually weaker, and died exhausted on April 27th.

NECROPSY.—The lungs (especially the left) were densely studded with miliary and caseous tubercles, scarcely any healthy tissue being left. Numerous small cavities were also present. The left middle

cerebral artery, opposite the third left frontal convolution, was occluded by a decolorised clot; and the cerebral substance immediately surrounding the obstructed artery was soft and slightly yellow. The heart was healthy. There were no tubercles elsewhere.

## REPORTS OF SOCIETIES.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 5TH, 1877.

CHARLES WEST, M.D., President, in the Chair.

*Calcified Fibroid Tumour of Uterus.*—Dr. ROPER showed a specimen of calcified fibroid tumour of the uterus; and a tumour of the placenta believed to be an organised blood-clot or a growth intermediate between myxoma and fibroma.

*Secondary Puerperal Hemorrhage.*—Dr. C. S. REDMOND described a case in which hemorrhage came on a month after confinement. The woman lost a great amount of blood. A portion of placenta was found in the uterus and removed, and perchloride of iron solution was injected. Some febrile disturbance followed, but the patient made a rapid recovery.

*General Dropsy in the Fœtus with Hypertrophy of the Placenta.*—Dr. BASSETT described a case. During labour, delay had occurred after the birth of the head. It was believed, after auscultation of the mother's abdomen, that the child was dead. Delivery was effected by drawing down an arm by the blunt hook. The child was greatly cedematous; the placenta large and hypertrophied, weighing three pounds and a half, and in twelve hours it discharged one pound of fluid.—Dr. JOHN WILLIAMS said that what we knew of the production of dropsy in the child was the result of our knowledge of the mode of production of it in the adult. Heart-disease never caused in the adult uniform general dropsy; that condition was always the result of a blood-state. The effect of central obstruction was to cause cedema of the most distant parts from the heart. In the fœtus, the placenta would suffer first. This would interfere with the flow of blood through that organ, and dropsy of the fœtus would follow. The placenta acted not only as an organ of respiration for the fœtus, but probably also as a renal organ; and anything which interfered with the circulation in it, or increased the thickness of its tissues, would interfere with the elimination of excrementitious products from the blood of the child. This would bring about a blood-condition similar to that met with in Bright's disease, and general anasarca in consequence.—Dr. EDIS thought that it ought to have been learned whether or no the child was dead without the aid of chloroform. The proper treatment was to have brought down an arm at once; the issue might then have been different.—Dr. ROPER said when a head had been born an hour or two without the body, the probability was the child was dead. The delay is due to disease of the fœtus, ascites, or something else. In that case, he would perforate the thorax and deliver.—The PRESIDENT regretted that no reference had been made to the researches of Simpson. New observations should be made and compared with those made before.

*Complete Rupture of the Perineum.*—Mr. C. R. THOMPSON described a case in which the arm of a dropsical fœtus appeared through the anus of the mother and ruptured the perineum completely. Deep sutures were at once inserted. On the third day, they were removed. On the fifth day, an aperient was given. The patient was perfectly recovered at the end of a month.—Dr. HAYES was in favour of the use of sutures in laceration of the perineum; he kept them in five days.—Dr. BANTOCK used silkworm-gut.—Dr. WYNN WILLIAMS used the first material at hand.—Dr. MURRAY recommended lateral incisions of the vaginal orifice with a view to prevent rupture.—Dr. EDIS thought that the treatment of the bowels was an important point. It was important to ensure regular action from the first. He used silver wire covered with gutta percha.

*Meningocele complicating Labour.*—Dr. S. WORDSWORTH POOLE described this case. Version by the bipolar method was tried, but ineffectually. The hand was then introduced into the uterus and version effected by the feet. At the back of the head was a large translucent cyst, measuring fourteen inches in circumference.

*Double Vagina and Uterus.*—Dr. HENRY GERVIS described a case of this kind. The patient had been married four years, suffered from dysmenorrhœa, and sometimes dyspareunia. There were two vaginæ, separated by a septum, from one-twelfth to one-eighth of an inch in thickness. The left vagina was larger than the right. At the top of each vagina was a cervix with a small os uteri. A probe could be introduced into the left for half an inch; into the right for an inch and

a half. There were two uteri present. The septum between the vaginæ was divided by the galvanic *crasseur*, with a view of relieving her suffering.

*Extra-uterine Pregnancy.*—Dr. HENRY M. MADGE said that, though there are differences of opinion with regard to the varieties of extra-uterine pregnancy, yet most cases may be referred to the tubo-ovarian and tubo abdominal. The author was of opinion, however, that the placenta may be developed within the ovary, and also when attached to the peritoneum. Mr. Jessop's case was clearly abdominal. In such a case, there are no decidua, and there can be no uterine sinuses nor ntero-placental vessels—the so-called curling arteries and veins of the size of crow-quills—passing from the peritoneum to the placenta; and, therefore, there must be an absence of what is called the sinus system. The membrane to which the placenta is attached allows interchange of fluids, and the nourishment of the fœtus is thus provided for. Nothing is known of the structure of extra-uterine placenta, but it is evident they must be all foetal. Many questions were raised by such cases as Mr. Jessop's, where the fœtus was not surrounded by membranes, such as the source of the liquor amnii, the origin of vernix caseosa, the disposal of the foetal urine, etc.

*Removal of Large Uterine Myomata by Abdominal Section.*—Mr. LAWSON TAIT gave an account of four cases of this operation. The first operation was performed on account of recurrent intestinal obstruction due to a myoma. The patient recovered. The next was the removal of a rapidly growing soft myoma, reaching nearly to the xiphoid cartilage, in a woman aged 45. The tumour was freely movable, with but few adhesions. The pedicle was clamped. The patient died on the fifth day after operation. It was found that the uterine cavity entered the tumour for about six inches. The third case was a patient aged 41, suffering from a multiple fibroid, reaching above the umbilicus. There was no distress, except occasional pressure on the intestines. The author urged her to leave it alone. She determined to have it removed, however, and the operation was performed on May 19th, 1877. The patient died on May 22nd. The last case was a patient suffering from a tumour of somewhat doubtful nature. A medical practitioner tried to tap it, and the tumour then grew rapidly, and the patient's health suffered in consequence. The tumour was removed, the pedicle being clamped; the patient made a good recovery.—Dr. FANCOURT BARNEFS had assisted at an operation for the removal of a fibroid complicating pregnancy. The tumour was in the pelvis. There was great difficulty in removing it. The patient died in five or six hours.—Dr. PLAYFAIR said that in two of the patients operated upon the diagnosis was doubtful. In one, it was done against Mr. Tait's advice. Why was it done? The course of fibroids was not usually fatal; and abdominal section should not be undertaken for their removal unless life was endangered.—Dr. ROUTH said the great point in this operation was how the pedicle could be secured. He had collected cases, and found that death was due to slipping of the ligature or clamp. The pedicle ought to be transfixed. The rule should be never to listen to what a patient said of the desirability of an operation. Unless there were danger, the operation was not justifiable.—Dr. BANTOCK said the feasibility of the operation depended on the presence of a pedicle. If the fibroid involved the body of the uterus, the operation was contraindicated. He recommended ligaturing the pedicle in small pieces by transfixion, each ligature linking to its neighbour like the links of a chain.

### EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, DECEMBER 12TH, 1877.

Surgeon-General JOHN MURRAY, M.D., President, in the Chair.

*Variolæ Anomale.*—Dr. COLLIE read a paper entitled "Variolæ Anomale" (Sydenham), with suggestions and reflections. He began by stating the object of his paper to be "to notice some points in which the recent epidemics resemble the great epidemics of the past; to call attention to the inefficiency of the existing vaccination law, and the grave dangers which may be incurred if this inefficiency be permitted to continue". After giving details of two cases of hæmorrhagic small-pox, one following an attack of scarlet fever, the other an attack of enteric fever, in both of which death took place suddenly and without any warning, he went on to show how closely such cases resembled the accounts of the black death of the middle ages, as given by Vinario and others. To his mind, there was no doubt that black small-pox and black death were identical; and he further thought that black small-pox formed the chief part of the plague of Athens, so graphically described by Thucydides. In recent epidemics, as well as in the present one, there had been a large and increasing proportion of black cases, and should vaccination be neglected, Dr. Collie thought that small-pox might again assume its mediæval virulence. He stated

that black small-pox occurs invariably in unvaccinated persons or in persons who have not been re-vaccinated after fifteen. He then gave the history of a case of what appeared to be, from the eruption, mild small-pox. The patient, aged 21, had two good vaccination-marks. Death occurred an hour after admission. The *post mortem* examination showed that the anterior part of the corpus striatum and the whole of the right hemisphere were ploughed up with blood. So far as he knew, this was the first case of the kind on record. Then followed a case of confluent small-pox, with extensive hæmorrhage into the vesicles, in a female aged 60, with no evidence of vaccination, in which, contrary to expectation, recovery took place. With regard to the compulsory vaccination laws, he thought that compulsory laws, which are practically not compulsory, were ridiculous, and that as regards vaccination, such laws served to retard, rather than to advance, its progress. Dr. Collie concluded by saying that no vaccination can be held to be efficient which did not include re-vaccination about puberty, and that vaccination should be the business of the State, and be performed by specially trained State officers, private practitioners, except in exceptional circumstances, being interdicted from vaccinating.—In the discussion which followed the reading of the paper, the PRESIDENT, Dr. C. E. SAUNDERS, Dr. MACKENNA, Mr. NETTEN RADCLIFFE, and Dr. ARGLES took part.

#### SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

THURSDAY, DECEMBER 13TH, 1877.

*Enlargement or Inflammation of Mediastinal Glands.*—Dr. GOODHART read a paper on enlargement or inflammation of the mediastinal glands. Four cases were narrated in which enlargement of the bronchial glands or thymus had existed in children, with marked paroxysmal dyspnoea, and in all of which death had apparently resulted from suffocation. In another case, similar enlargement in an adult, due to acute inflammation, was thought to explain coma and other symptoms of defective function of the medulla oblongata and pons Varolii: viz., staggering gait, defective speech, difficult deglutition, salivary dribbling, and disturbed cardiac rhythm. The author called attention to the fact that many of these cases of bronchial adenopathy occurred in robust-looking children; and he drew the conclusion from this, that the origin of the enlargement was a state of continued overfeeding, and suggested that neither this form of the disease nor tabes mesenterica were necessarily to be treated with cod-liver oil and steel-wine. These remedies tended to make matters worse rather than better in some cases; and restriction of diet, both in quality and quantity, often did more than medicine. He next discussed the pathology of the affection, and considered that the theory of reflex paralysis, advocated by Brown-Sequard in genito-urinary affections, held good here; and that, as a consequence of the involvement of the peripheral branches of the vagus, which was shown to be present, there was a central arterial spasm or immediate irregular nervous discharge; and thus the various morbid phenomena observed in these cases came about. He considered the paroxysmal dyspnoea due to a muscular spasm all through the lung, not merely to a glottic spasm; and, with regard to the more serious condition of coma, this also might be occasioned in a similar manner, and some corroborative proof of this was afforded by certain instances of sudden death after surgical interference with the pleura. He did not think, however, as some would appear to do, that all forms of paroxysmal dyspnoea in children were due to enlargement in the mediastinum: on the contrary, some appeared due to central and possibly epileptic disturbance, others to various peripheral stimulants, of which glandular enlargement formed only one. Under the head of treatment, discussion was invited upon the following lines. 1. Tracheotomy is of no use in urgent inspiratory dyspnoea, a fact strongly pointing in favour of the effective spasms being not in the glottis alone. 2. If any remedies are useful, belladonna in large doses, twenty or thirty drops of the tincture, repeated every three or four hours, is the most promising. 3. With respect to diet, starving is better than stuffing in some cases. In concluding, the difficulties of diagnosis were alluded to, and the impossibility in most cases of establishing anything upon a sure basis by means of percussion.—Dr. PHILPOT said that the same general symptoms were produced by other causes, and that the diagnosis was only to be made upon the *post mortem* table.—Dr. DUNCAN inquired whether there was any diabetes in these cases, which was a symptom of irritation of the vagus.—Mr. DIVER inquired as to the class of patients in which these cases were found; he would rather alter the character than lessen the quantity of the food.—Dr. GOODHART would hope, by severe cases, to prove points in other cases of inspiratory crow. There was no diabetes in the man. The form of dyspnoea would not distinguish cases. These occurred among poor but perfectly healthy-looking children.

*Sayre's Plaster Jacket.*—Mr. MARSH exhibited Dr. Sayre's method of treating spinal curvatures with the plaster-of-Paris jacket, and gave his experience of its use. He had applied it in six or eight cases of lateral and in about twenty of angular curvature. All the patients had been between three and fifteen years of age. He had had no opportunity yet of employing it in the adult. In lateral curvature, where the use of the jacket was combined with careful suspension, as recommended by Dr. Sayre, twice a day, he thought it quite proved that it was the best appliance that had yet been brought before the profession. In two of the cases he had mentioned, lateral curvature was extremely marked. In the first of these, that of a girl aged thirteen, the curvature had commenced when she was three years old, and had continued to increase in spite of the usual steel support, with arm crutches, and means for lateral pressure. In the other, a boy aged fourteen, the curvature had resulted from an empyema, which had discharged for three years. Here also the steel support had proved useless. In both, there was a great contrast as to the comfort with which the rival apparatus were worn. The steel supports had produced painful spots on the skin in several places, and had caused considerable distress. The jacket, however, was borne without any kind of inconvenience. Both patients were taller by rather more than one inch after the jacket was applied than before. The girl had worn the plates for four months, and during that time her general health had much improved; she could now take long walks and active exercise, and her mother stated that her voice had become much stronger. In the remaining cases, the children, who were out-patients, had all worn the jacket without any kind of inconvenience and with marked benefit. In the cases of angular curvature, the result of the treatment had on the whole been satisfactory. Many of the children had been able to take exercise, and had felt no pain or discomfort; in some, however, the jacket had not removed pain, and the treatment by rest in the recumbent position had been resumed. This method of treatment could not, he thought, be safely employed, unless the patients could be kept under very careful watching; and he had seen two cases in which ulcers formed from pressure on a projecting point of the spine. And the utmost gentleness and care were absolutely necessary in suspending the patient while the jacket was being applied. Children generally felt relieved when the spine was gently and very slightly extended; but, if the extension were either sudden, or more than very slight, great damage might be done; and, as soon as the plaster had hardened, openings should be cut opposite all prominent points, so as to relieve the skin from pressure. The jacket was not suitable for curvatures in quite the lower dorsal and lumbar regions of the spine; for, when the disease was thus low in the column, no adequate *point d'appui* could be obtained for the support of the trunk and upper limbs. But some cases had occurred in which very striking relief had followed when disease was in the upper dorsal and cervical regions. Dr. Sayre's "jury-mast" was in many instances very useful. A great difficulty, and one which it seemed very hard to deal with, was met with in children. The abdomen was frequently very prominent, and also liable to considerable variations in size, so that only very imperfect support could be obtained for the anterior and lower segment of the jacket, which was sometimes found to become very loose when the abdomen was less distended. This circumstance had seemed to render the support quite useless in some cases; in two or three instances, too, the jacket had gradually slipped down, the pelvis in children being small and with its prominent points little marked. In only one case had there been anything to suggest that the jacket might dangerously impede respiration. When the patient, who had formerly had empyema, was suspended, the shape of the thorax was so much changed that his breathing was seriously embarrassed, and the jacket was therefore at once removed; but next day it was again put on, while he was very slightly raised, and was then borne without any kind of discomfort, and no further trouble of any kind ensued. Yet this case showed that great care should always be taken against this possible source of danger; and he thought some means should always be at hand for removing the jacket, should it be necessary to do so. There were many points respecting this method of treatment in which further experience was required; but, on the whole, he thought it very valuable, and worthy of extended trial.

*Calomel as a Medicine.*—Dr. LANCHESTER read some remarks on calomel as a medicine. After stating that fashion had been against calomel of late, he remarked that its evils had been exaggerated, and, in attempting to do without it, we were depriving ourselves of an useful medicine. Calomel was spoken of as an alternative, but its best known effect was purgative. As a cholagogue, there was no increase of bile or stimulation of liver; and the bile, after its use, was due to rapid action preventing the ordinary changes of bile in the colon. As an antiphlogistic, he contrasted Sir T. Watson's "sheet-anchor in inflammations" with Mr. Holmes's "no power to resist inflammation, but

induces cachexia, which prevents adhesive formations". Calomel was a diaphoretic, diuretic, and sedative; useful as a purgative in children, from small dose and freedom from colour or smell. He found it very useful in gastric catarrh, with rapid pulse and rise of temperature; in dentition, with confined bowels; convulsions, with throbbing fontanelle; and in croup; and, with other aperients, in worms. In adult life it gave great relief in sluggish liver, in gouty persons, in cases simulating puerperal fever, urgent sickness in peritonitis, in red and cedematous throat. In congestion of the liver, he advocated its use as a convenient purgative, not continued. In acute gout and rheumatism, he gave a full dose at the commencement. In syphilis, he gave a course of mercury, and in this way it was stated to be a means of warding off megrim. He relied upon the drug principally for occasional use, but was loth to practise the continued use of a medicine which was not a natural constituent of the blood.—Dr. PHILPOT affirmed that doubt about the effect of medicine was generally due to ignorance of the natural course of disease. Calomel was the most valuable form of mercurial in syphilis. He followed Ricord's plan to keep under treatment for one year, avoiding salivation, giving one-third of a grain of calomel three times a day.—Mr. BERNEY had adopted the calomel treatment in two epidemics of Asiatic cholera, the sign of recovery being sea-green tint of the evacuations.—Dr. PARSONS-SMITH drew attention to peculiarities of constitution, which rendered some more liable to evil effects of mercury.—Dr. DUNCAN inquired whether there was any ground for the idea of peculiar susceptibility to cold after mercury.—Mr. NAPPER had never given up the use of calomel, and alluded to its use in laryngismus stridulus.—Dr. HOLMAN gave with great advantage one-twelfth of a grain of calomel, every hour, to children with intestinal catarrh, attended with profuse pumping-up of the contents of the stomach. He had also used calomel as a sedative.—Mr. HEARNEN advocated local use of calomel in phlyctenular ophthalmia, also internal in the vomiting of pregnancy.—Dr. COLES thought that too much importance was attached to the experiments of Dr. Bennett on mutilated dogs. In children with aggravated sickness and diarrhoea, he gave one to two grains of calomel.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

NOVEMBER 23RD, 1877.

JAMES THOMPSON, M.B., President, in the Chair.

*Prolapse of the Bowel.*—Dr. JOY (Tamworth) read notes of a case of prolapse of the bowel in the adult. The case was published in the BRITISH MEDICAL JOURNAL of December 15th.

*Skin-grafting.*—Mr. ALEXANDER HAWKINS showed a male patient, aged 30, who had been admitted three months previously into the General Hospital with diffuse cellular inflammation of the forearm, followed by sloughing of the entire thickness of the skin of the back of the forearm, the slough extending from the elbow to the wrist. After he had been in the hospital seven weeks and the large raw surface had assumed a perfectly healthy appearance, skin-grafting was commenced. About one hundred grafts were applied, most of them taken from the cadaver. The surface was healed over in five weeks, except four little patches, each about the size of a sixpenny-piece.

*The Use of Alcohol in Disease.*—Dr. RUSSELL read a paper on the use of alcohol in the treatment of disease. He considered the subject in four relations, viz., the historical, the moral, the scientific, and the practical. He referred to the great changes in opinion as regards stimulating and depleting in the treatment of disease which had taken place during a single generation, as suggesting caution in opinion and forbearance in discussion. Under the second head, he dwelt upon the responsibility which the present tendency to licentious indulgence attaches to the prescribing of alcohol, and pointed to some important limitations, whilst expressing the opinion that the share attributable to the profession in inducing intemperance among out-patients had been much exaggerated. From the scientific point of view, the observations of Baudot, of Anstie and Dupré, and Binz were quoted as having corrected previous objections against the utility of alcohol, grounded on the supposition that all the alcohol taken was excreted unchanged; and, referring to Dr. Frankland's estimate of the force-producing power of alcohol, he noticed its capacity for developing energy within the system, and connected this capacity with Anstie's definition of stimulants and his arrangement of food at the head of that group. The power of alcohol as a cardiac stimulant, as a vaso-dilator, and as an antipyretic, was briefly noticed; and the paper concluded with caution against the too unlimited influence of the purely scientific aspect of the question, and the necessity of checking that influence by certain practical considerations which were shortly recounted.

WEDNESDAY, NOVEMBER 7TH, 1877.

F. OGSTON, M.D., President, in the Chair.

*Digital Dilatation of the Os Uteri as an Aid to Labour.*—Dr. LYON had come, from large experience, to the conclusion that digital dilatation of the os was no aid to labour; and he thought the following reason explained this. During pregnancy, the cervix had an internal and an external opening, and, forming no part of the cavity of the uterus, was under the influence of the reflex action of the spinal cord. When labour commenced, the cavity of the cervix became completely obliterated, and the os, instead of being an opening from a canal, became a hole in the wall of the uterus and the direct outlet of its cavity. By the process of thinning and expanding, the os gradually enlarged till no trace of it could be found. The distended bag of membranes seemed to exert some influence in dilating the os, but this was chiefly brought about by the uterine longitudinal fibres. While these changes were taking place on the lower part of the uterus, constituting the first part of natural labour, there was always an accompanying state of the body of the uterus characterised by regular contractions gradually increasing. This process of dilatation, etc., was never affected by the kind of presentation. But, in all cases of labour characterised by rigidity, and a consequent dry and unyielding state of parts, there was want of dilatation; and all efforts, digital or otherwise, were ineffectual so long as the attendant pains were irregular and without downbearing tendency. After more or less delay, when pains became regular and expulsive, the parts became lubricated with mucus, soft and yielding; and the dilatation was then speedily effected, and not till then. He had often tried to dilate the os with the finger in those tedious cases, and must, had he persisted, have simply torn the part. He had also succeeded in slipping the stretched os over the occiput, but these efforts had no beneficial effect on the labour. He thought it not improbable that the want of dilatation in such cases might arise from increased tonic contraction of the os caused by some continued peripheral irritation, and thus would be explained the beneficial effect often produced by removing accumulated faeces by enema. He inferred from what he had observed that want of dilatation was no cause of hindering the progress of labour, and that the want of dilatation was owing to the state of the uterus characterised by the absence of true labour-pains, and disappeared on their occurrence. Venesection and nauseating doses of emetic tartar had been used to facilitate dilatation, and more recently chloral and chloroform; and, if the object of treatment were to relieve a state of spasmodic contraction, these means appeared more likely to effect the purpose than digital efforts. If the os could yield to the gentle pressure of the finger, why did it not yield to the pressure from above? The necessity for digital interference never existed at all except in rigidity, and then it was impracticable. If it were to be used at all, Burns's rule was the only safe one, "If the os uteri be lax and thin or soft, it is both safe and advantageous to dilate it gently with the finger during a pain"; and, if we got the parts into the condition Burns indicated, there would be no difficulty in producing dilatation, because the cervix, which before was unyielding, had assumed the condition of natural labour and needed no interference.—Dr. GEORGE agreed with Dr. Lyon. The only thing he had found useful was smearing extract of belladonna on the rigid os.—Dr. COLLINS had not found in his experience dilatation of much service.—Dr. HIRSCHFELD thought digital dilatation was often impossible. He had found dry cupping the back very beneficial in cases of rigidity and dryness of the parts. He thought the presentation had much to do with it.—Dr. ALEXANDER REITH had been in the habit of dilating with two or three fingers, and always had the os yielding and papery in ten minutes. He first introduced two fingers and stretched them, and then three. This was done *between*, not *during*, the pains. He was in the habit of rupturing the membranes as soon as he arrived in every case, and had found this very useful.—Dr. GARDEN thought there was no doubt as to dilatation producing pain; but he was inclined to question its power in hastening the labour.—The PRESIDENT thought dilatation with one finger during a pain was not valuable, as indicated by his own experience. He could not say anything regarding the effect of two or more fingers during the interval.—Dr. STEPHENSON said that dilatation was good to remove the valve or diaphragm; but in the earlier stage, if there were a real cervix, then working at the os only could do no good. Dilatation could be properly practised only after the cervix was obliterated. The size of the os was not to be regarded, but the state of the cervix. If the lower segment of the uterus were not fully expanded so as to let the head down, there was no use in dilating. In great agony or sickness, chloral or chloroform should be given, or cupping might be used, but he would not use belladonna. When, however,

between the operator and the head there was nothing but a diaphragm, then was the time for dilatation. During a pain, the cervix was to be slipped over the occiput, and then, the other part being over the forehead, a more downward tendency is given to the occiput, and labour is facilitated. He thought the pre-entation was very important as to rapidity of labour, occipito-posterior and breech cases being much slower. As to the time of rupturing the membrane, he thought this should be done when the lower segment of the uterus was expanded.—Dr. LYON, in reply, said that at one time he thought the membranes were of some use, but he did not now believe it. The os opened quite well with arm and shoulder presentations by means of the longitudinal fibres. He saw no difference between one, two, and three fingers. He did not think the os not being open was the obstacle; it was the irregular pains which caused the delay; for, as soon as the pains became regular, the os opened, and the parts became moist and natural.

*Three Cases of Tetanus, with Remarks.*—Dr. COLLINS of Bervie reported these cases. Case I might not by some be considered as a case of tetanus; but it was given chiefly to illustrate the power of Calabar bean in relaxing tonic muscular spasm. An old man aged 80 had an attack of apoplexy and right hemiplegia on January 4th, 1870. He gradually recovered to a certain extent, with slightly thick articulation and some power in the limbs, though never to the extent of walking. On June 4th (five months after the attack), he was seized with what he called "cramp," but which had more the character of tetanic spasm, depending probably on an unabsorbed fibrinous clot. Rubbing and warmth were observed to increase the severity of the spasms. The affected limbs, which before were limp, became rigid. Five-grain doses of Calabar bean powder were given every two hours, and these were continued for five doses, when complete relaxation took place, and he slept quietly for several hours. On awaking, the spasms recommenced, increased in severity, and extended to the left side. Other five doses had to be given as before, and then he slept again. From day to day, the spasms returned, each time more extensively; and the Calabar bean, though continued, lost its effect. On the 15th, he lost the power of swallowing; and on the 18th he died exhausted. The most remarkable feature in the case was the long period between the injury to the brain and the symptoms.—Case II. This was a case of traumatic tetanus in a boy about five years old. He was dragged along the road in front of a farmer's roller on which he was riding, and had his right thigh abraded, the skin not being entirely removed. A poultice was applied, and he went on well, the wound granulating, till the ninth day, when Dr. Collins found his jaws clenched and slight spasmodic rigidity of the limbs. Three grains of Calabar bean were ordered every two hours till relaxation took place. During next day, he seemed but slightly relieved; and the day after the spasms became much more severe, and chloroform was administered intermittently for over two hours whenever the spasms would allow, and he then fell asleep and slept throughout the night. On the fourth morning, he was free from spasms, and the powders were ordered to be continued. During the same afternoon, however, a severe attack came on, and he was dead before he could be seen. In this case, the symptoms increased rapidly from the first, and the bean had little effect, in the doses given at any rate. Chloroform seemed useful; and, had it been at once given on the coming on of the final attack, the fatal result might, perhaps, have been averted.—Case III. A healthy active boy, aged about 8, fell from a wall and cut the sole of his right foot on a piece of broken bottle. The wound was dressed; and healed by first intention in a few days, except behind the ball of the great toe, where there was a slight suppurating wound. The dressing was renewed, and not disturbed for eight days more, when the whole was found healed. In about ten days, he became affected with trismus and tonic contraction of the muscles of the face and neck generally. Although there was no pain, etc., in the foot, it was constantly poulticed, the room was ordered to be darkened, and all excitement to be avoided. He had ten grains of chloral-hydrate every two hours for four times, and then he slept throughout the night; and after this he was kept constantly under the influence of chloral, being roused at intervals to take food and medicine. After the first day, he had ten grains of chloral and ten grains of bromide of potassium every three hours, and thus slept almost constantly for the first week, at the end of which time the rigidity began to give way. The medicines were then diminished in frequency, and he continued steadily to improve until he became quite well. This case might be considered slight and the prognosis favourable, and the length of time between the wound and the coming on of the symptoms was undoubtedly encouraging, yet it was doubtful if the patient would have recovered without treatment. It had been held by great authority that such cases never recovered spontaneously; and, therefore, chloral-hydrate might fairly be credited with the cure.—Dr. FRANCIS OGSTON,

asked if no symptoms of irritation of the stomach arose from the chloral administered for some time in one of the cases.—The PRESIDENT remarked that he had found chloroform of no use.—Dr. ALEX. OGSTON had for some time given up regarding tetanus as a nervous disease, and was inclined to consider it to arise from blood-poisoning. Hence, the spasms were like the rigors of fever; and, although we might prevent the spasm, yet the patient died as if nothing had been effected. He had not seen any good practical results as yet from the view he took. He hoped something from salicylic acid, but had not tried it yet. Amputation and other local means he had found of no value.—Dr. HIRSCHFELD had seen several cases, but had never seen a bad case recover. He had seen two recoveries; one in the Franco-Prussian war, and the other in the Edinburgh Hospital. In the former, no wound could be discovered; and in the other a small piece of glass was the irritant. He did not think the symptoms had any connection with blood-poisoning. He wished to know if the Calabar bean had been pushed to the extent of contracting the pupils.—The PRESIDENT had examined cases coming under his notice very carefully, and had found thickening of the nerve only. The wounds healed very easily.—Dr. COLLINS agreed with Dr. Alexander Ogston as to the cause being blood-poisoning. He had not found the chloral produce any irritation of the stomach. The Calabar bean had contracted the pupils.

*Cases of Scarlatina with Diphtheria.*—Dr. GEORGE of Keith related these cases as examples of complications of scarlet fever and diphtheria, and of the modes in which these diseases were propagated in a country district. He held that scarlet fever and diphtheria could be conveyed not only from one person to another, but by cats, dogs, etc., which ought to be shut up during the prevalence of these diseases. In his locality, he had found it impossible to prevent the females from conveying infection from house to house. During April and May 1876, a number of families in a healthy locality were attacked with scarlatina and diphtheria. In the scarlet fever cases, the rash was well marked, and the throat affection was quite different from that in the diphtheritic cases, the specks being less coherent and spreading simultaneously over all the mouth, whereas in the diphtheritic cases there was the appearance of false membrane, circumscribed at first, and then going into the larynx. The scarlet fever cases were not prostrated as the diphtheritic cases were; and were with difficulty kept in bed. Albumen was in the urine of all the scarlet fever patients. The treatment of these was gentle purging, liquor ammoniac acetatis, mistura camphoræ, infusion of dulcamara, and sponging the body with vinegar and water. The diphtheritic cases were treated with strong solution of nitrate of silver locally, and copper, quinine, and iron internally, with wine and whisky. Most were convalescent in a fortnight. A few, with whom it was otherwise, he gave more in detail. He wished to bring copper very prominently under the notice of the Branch as being a far more powerful tonic than iron, and to claim a high place for decoction of dulcamara as a sedative in scarlatina.

#### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

THURSDAY, NOVEMBER 22ND, 1877.

G. RIGDEN, Esq., in the Chair.

*Poisoning by Yew-Leaves.*—Mr. T. WHITEHEAD REID, in the course of a paper on a case of poisoning by yew-leaves, drew attention to the caution given in the Scotch Lunacy Blue Book for 1875, to avoid yew, either as decorations or as growing shrubs in asylums. In the Cheshire County Asylum a death occurred within an hour or two after taking the yew; five grains being the total quantity found. In Mr. Reid's case the quantity collected from the stomach and dried weighed twenty-two grains.

*The Forceps in Midwifery.*—Mr. RIGDEN read a report of the last 200 obstetric forceps cases that had occurred in his practice during the last eighteen years; the proportion being about 7 per cent. of the total number of labours. The forceps cases had been generally those in which there was either considerable inertia or marked disproportion, and yet there had been no maternal death, and but nine stillbirths. He advocated the more frequent use of the forceps than was generally taught, the object being to assist, and not, as some practitioners imagined, to interfere with Nature. His experience had taught him that the dangers of the forceps were not in its early use where there were no contraindicating circumstances, but in the delay in its application, as the operation certainly prevented much additional suffering and anxiety to the mother, and was a preservative of the life of the infant. His practice was to make as little ceremony as possible about its application; generally to have the forceps with him if likely to require it, and to inform the patient that there was no danger in its

careful employment. He deprecated the delay as well as the alarm caused to the patient and her friends by calling in further advice, or by making much ceremony about the application. He believed that obstetric practitioners are now much more than formerly in the practice of using the forceps; and his object in bringing the subject before the meeting was to instil more confidence in its employment.—Dr. LEWIS thought that the use of the forceps once in fifteen cases was unnecessary, and that the interference was excessive.—Dr. BOWLES was of opinion that the forceps was more frequently used at the present day than it was a few years ago; and that this earlier and increased use of the forceps was justified by experience. The general feeling of the meeting coincided with this view.

## GLASGOW MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, DECEMBER 7TH, 1877.

EBEN WATSON, M.D., President, in the Chair.

**Popliteal Aneurism.**—Dr. PATTERSON read notes of a case of popliteal aneurism, which recurred three days after ligation of the superficial femoral. As pressure over the artery in Hunter's canal caused all pulsation in the aneurism to cease, the vessel was ligatured in that region twenty days after the first operation with the result of completely curing the disease.—The PRESIDENT related a case of his in which pulsation returned after ligation of the superficial femoral, and in which he also tied the vessel in Hunter's canal with no effect, and consequently he was led to tie the external iliac, which cured the aneurism; but gangrene of the limb ensued, necessitating amputation.—Dr. G. H. B. MACLEOD mentioned a case of multiple aneurisms over the whole body, in which, at the earnest entreaty of the patient, he amputated one thigh, in which there were three aneurisms, the result being a permanent cure of all the others. He also detailed the case of a sailor with a popliteal aneurism, who, without consulting any surgeon, bent his leg to ease the pain; after keeping it so for two days, he found that all pain had ceased, and the large swelling at the back of his leg was quite firm. This case was interesting with reference to the treatment of such cases suggested by Mr. Ernest Hart. Dr. Macleod doubted the advisability of taking Dr. Patterson's case as a precedent for ligaturing in Hunter's canal after failure of operation at apex of Scarpa's triangle, as by so doing no additional vessel was commanded, and he could only account for the success of Dr. Patterson's case by an unusual arrangement of the vessels.—Dr. A. M. BUCHANAN stated that, in an anatomical point of view, he agreed with Dr. Macleod, and he would rather have recommended ligation of the internal iliac.—Dr. HECTOR CAMERON thought that in a similar case, he would be inclined to adopt Dr. Patterson's line of treatment, as the fact that pressure in Hunter's canal caused cessation of pulsation was sufficient indication that ligation would be successful.—Dr. WATSON stated that, as in his case, pressure causing absence of pulsation was not a certain sign that ligation would be successful.—Mr. REID asked if the first ligation, which was catgut, could not have slipped.—Dr. PATTERSON did not think this possible, as there was no pulsation in the femoral at the site of the first operation.—Dr. RENTON showed a sphygmographic tracing of the aneurism.

**Hydrophobia.**—Dr. PERRY read notes of a case of hydrophobia, the symptoms of which commenced ten months after the patient—a female—had received a bite on the hand from a dog. The patient died twenty-four hours after the symptoms manifested themselves. Dr. Foulis made a *post mortem* examination of the body, and the organs were recommended to be sent to the Committee at present investigating the subject.—A discussion took place, in which Drs. J. COATS, MACLEOD, and CHARTERIS took part. [The above case is the first which has happened in Glasgow for many months, due, in all probability, to the vigorous efforts which the sanitary authorities have made to destroy all stray or suspicious dogs.]

## NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, DECEMBER 13TH, 1877.

G. B. MORGAN, Esq., President, in the Chair.

**Prevalent Diseases of the District.**—Mr. H. E. ARMSTRONG (Medical Officer of Health for Newcastle-on-Tyne) presented a report of the cases admitted to the Fever Hospital during the month of November, and stated that the town was healthy.—Mr. SPEAR (Medical Officer of Health for South Shields, Jarrow, and Hebburn) stated that scarlet fever was epidemic at South Shields. In several cases, the disease had been propagated by children being sent to school while still convalescent.—A committee, consisting of the President, Mr. Spear, Mr. H. E.

Armstrong, and Dr. Byrom Bramwell, was appointed to consider the subject and to report to the Society.

**Pathological Specimens.**—Dr. ANDERSON showed three calculi removed by lithotomy. The first patient was a boy aged 4½, the second a man aged 32, the third the boy mentioned as Case 1. Symptoms of stone returned in eight months, and the second operation was performed nine months after the first. All three operations had done well.—Dr. PAGE showed two Salivary Calculi removed from Wharton's duct by a free incision. Dr. Page also showed an Urethral Calculus, which had become lodged behind a stricture. The stricture was split up by Holt's dilator, and the stone was then expelled with the urine.—Dr. ARNISON showed two Calculi removed by lithotomy from the same patient, a child aged 3, at an interval of a year. After the first operation, the bladder was carefully examined and found to be empty.—Mr. HORGWOOD showed a recent specimen of Placenta Prævia. The gestation had advanced to the fourth month, when severe flooding came on. The case had done well.—Mr. MORGAN showed a specimen of Encephaloid Disease of the Femur.—Dr. EMBLETON showed several Photographs of Monstrosities.

**Exhibition of Patients.**—Dr. BYROM BRAMWELL showed a case of Congenital Microphthalmos of the left eye.—Dr. HEATH showed a case of Hypertrophy of the Tongue.

**Papers.**—Dr. EMBLETON read the notes of a case of Empyema treated by a free incision under antiseptic precautions. The patient, a boy aged 16, recovered well.—Dr. MURPHY read the notes of two cases of Chlorodyne-poisoning.—Dr. D. DRUMMOND read the notes of a very interesting case of Paralysis of the Pharynx occurring in a child aged fourteen months, and suggested that the paralysis was due either to lead-poisoning or to diphtheria. The child was in the habit of sucking a leaden bottle, and there was a history of ulcerated sore-throat.—Dr. BYROM BRAMWELL continued his paper on Intracranial Tumours, relating three additional cases.

## SELECTIONS FROM JOURNALS.

### MEDICINE.

**SMOKERS' GASTRALGIA.**—M. Révillout reports in the *Gazette des Hôpitaux* two cases of gastralgia attributed to the use of tobacco. The first case occurred in a man aged 52, in M. Vulpian's wards. He had always been moderate in everything except the use of tobacco, had never undergone any privation, had always been able to choose his food, and had been careful in his diet. On six different occasions, he had been seized with extremely acute attacks of pain in the stomach, not extending to the back, and coming on more or less quickly after every meal, bringing on also vomiting of the food. In the intervals of these attacks, of which the average duration was about six weeks, his health seemed tolerably good, with the exception of some vertigo, dazzling of the sight, and weakness of the legs. These troubles were more marked when the patient felt better and smoked than when, suffering with gastric troubles, he had no appetite for anything and temporarily left off tobacco. M. Révillout also reports a case in which a gentleman in good circumstances, following an excellent hygienic system, found his digestive functions gradually failing, whilst his strength diminished. Later on, he was attacked with vertigo, staggering whilst walking, and spasms and prickings in the limbs. After every meal, severe pain was felt in the epigastric region; the face was pale, the speech gasping, the heart-beats uncertain, and the body generally discoloured. This patient smoked from twelve to fifteen cigars daily. Under advice, he reduced this number to two, and immediately a considerable improvement took place. He again took to excessive smoking; but, as the original symptoms returned, he was again obliged to abstain from tobacco. Under medical advice, he washed the tobacco of which he made his cigarettes in a coffee-percolator, by first throwing on it ammoniacal water, then repeated baths of hot water. The nicotine was thus partly dissolved out of, or mechanically removed by, the warm water. The tobacco, when washed, was spread out in the sun to dry on paper, and thus modified satisfied the patient, who from that time was not troubled with dyspepsia or vertigo.

**LESION OF THE PANCREAS IN CERTAIN FORMS OF DIABETES.**—At a recent meeting of the Paris Academy of Medicine, M. Lancereaux showed some pathological specimens of lesion of the pancreas in patients who had died of diabetes, and gave the history of the cases. He said that the cases and the specimens showed that diabetes mellitus is, at least in some cases, accompanied by a serious change in the pancreas. A similar change has been met with in many other cases of diabetes; and in these cases, as in those noted by M. Lancereaux, the

disease, of which the course has been comparatively rapid, has shown itself by excessive appetite and thirst, great emaciation, profuse glycosuria—in a word, by all the characteristics of diuretic wasting. On the other hand, animals the pancreas of which is extirpated or destroyed become voracious, are rapidly emaciated, and succumb very quickly. Taking, therefore, into consideration the special characters of diabetes in cases of disease of the pancreas, and the phenomena in animals following the destruction of this organ, M. Lancereaux thinks it may fairly be concluded that there exists a causal relation between serious changes in the pancreas and the diabetes mellitus in question. This form of diabetes is distinguished by the comparatively sudden appearance of emaciation, with polydipsia and excessive appetite, and peculiar characteristics of the alvine excreta. The prognosis of this form of diabetes is very unfavourable. The indications of treatment consist in prohibiting the use of articles of food which are digested by the pancreatic juice, and nourishing the patient with that class of food which is digested in the stomach.—*La France Médicale*, November 17th.

**PARALYSIS OF THE RIGHT SPINAL ACCESSORY NERVE**—In a dissertation (Berlin, 1877), B. Holz describes the case of a man who, previously in good health, was suddenly seized, after exposure to cold, with weakness of the right arm. On the same day, he also began to suffer from difficulty in swallowing. The right shoulder was lower than the left, and could be only slightly raised. The right trapezius and sterno-cleido-mastoid muscles felt flabby, although they reacted well to the electric current. The angle of the right scapula lay nearer the spine than that of the left; the upper part of the bone, however, stood further out. The left half of the palate appeared narrower and more arched than the right; the uvula deviated to the right; the left half of the palate alone moved; the right, even during rest, was farther from the pharynx than the left. The speech was not nasal, although there was difficulty in swallowing. The sensibility of the pharynx was normal, as was also the motor power of the right side of the face. The right vocal chord was paralysed; the sensibility of the laryngeal mucous membrane was increased; the voice was not hoarse. The pulse was persistently accelerated, though but slightly. Iodide of potassium and faradisation greatly improved the patient's condition. In Holz's opinion, there was rheumatic paresis of the accessory nerve, the seat of the lesion being in the trunk of the nerve a short distance beyond its exit from the skull.—*Centralblatt für die Medicin, Wissenschaften*.

### THERAPEÛTICS.

**TREATMENT OF BLENNORRAGIC EPIDIDYMITIS WITH IODOFORM OINTMENT.**—Dr. Alvarez de Palma (Majorca) has treated four cases of epididymitis with iodoform ointment, and from his experience draws the following conclusions. 1. Iodoform calms the pain of blennorrhagic orchitis better than any other application; this result is obtained at the end of one or two hours. 2. Iodoform exerts a very manifest resolvent action, and has the advantage over the usually employed mercurial ointment of causing no trouble when absorbed. 3. The iodoform treatment shortens very appreciably the duration of the orchitis, and prevents any consecutive induration of the organ. 4. It is necessary to employ an ointment containing, according to the intensity of the inflammation, from one to two grammes of iodoform to thirty grammes of lard.—*New York Medical Record*, October 13th, 1877.

**TREATMENT OF TETANUS BY CHLORAL-HYDRATE.**—Dr. Roberts, in the *American Journal of Medical Sciences*, October 1877, discusses this treatment. He says that, the prognosis of the disease being most unfavourable according to the best authors, "it must be acknowledged that to a remedy under which several successive cases recover there must be accorded a certain modicum of honour". Dr. J. B. Beck has collected thirty-six cases of traumatic tetanus treated essentially by chloral, in which twenty-one recovered. Dr. H. C. Wood has tabulated eighteen additional cases, with nine recoveries. Dr. Macnamara, in the *Practitioner*, November 1872, reports twenty successive cases of (? idiopathic) tetanus in India, of which seventeen recovered, all being treated by large doses (30 to 40 grains) of chloral. Vernel reports instances of cure where 100 grains, and even 245 grains, were given daily. One patient recovered, having taken six ounces of chloral in thirty days. Dr. Roberts now records nineteen cases of traumatic tetanus treated in four years at the Pennsylvania Hospital, of which only three were treated essentially with chloral, and these three recovered. The others were treated with morphia, atropia, cannabis Indica, calomel, conium, etc. A case is also reported, in the *Boston Medical and Surgical Journal* of October 4th, as having occurred in the practice of Dr. G. W. Gay at the Boston City Hospital. The

patient was a young woman aged 21, who had a cystic tumour of the left cheek treated by excision and slight counterirritation with nitric acid on May 14th. Everything went on well, and the patient was discharged in ten days with the wound nearly healed and the sac obliterated. In less than a fortnight after leaving the hospital, she began to notice a little difficulty in opening her mouth. The stiffness of the jaws gradually increased till June 25th, when she had three spasms in rapid succession, and was readmitted. Her mouth was firmly closed. Sixty grains of chloral were given her in divided doses, and the next morning she could open her mouth three-fourths of an inch. The pupils were widely dilated, and the patient was very drowsy. Half a drachm of the bromide of potassium every three hours was ordered in place of the chloral. At the end of forty-eight hours, she was scarcely able to separate the jaws. Chloral was added to the bromide of potassium in quantities sufficient to keep her drowsy, and was administered for ten days. On being allowed to come from under the influence of the drugs, she had another spasm, the last one of her illness. Chloral was given at intervals in scruple-doses for a week, when all medicines were discontinued. The patient received from forty to one hundred and sixty grains of chloral daily, and towards the last she became very delirious at night. There was no failure of the heart's action at any time. The disease gradually wore away, and in forty days the patient left the hospital, free from pain, able to open her mouth an inch, and to chew soft food.

**CONTINUOUS CURRENTS IN THE TREATMENT OF ULCERS, AND PARTICULARLY ATONIC ULCERS.**—The following cases are published by M. Staes-Brame in the *Bulletin Médical du Nord*. The first is that of a man aged 30. He had suffered for two years from large atonic ulcers on the legs. M. Staes-Brame had entirely cured one of the ulcers and greatly ameliorated the other by prolonged rest, compression, and tonics. That of the right leg, which formerly measured four inches by three-quarters of an inch, was reduced to a small wound less than two-fifths of an inch in diameter covered by a cicatricial pellicle, when, by some unknown cause, in twenty-four hours the whole of the former surface of the ulcer became denuded and discharged bloody serum. M. Staes-Brame determined to apply the constant current. He covered the wound with a plaque of metal, which he put into communication with the negative electrode, the positive pole being applied to the skin of the thigh. In ten minutes, the wound became pale; the next day, it had diminished by one-half; reapplication of the current for ten minutes, and the following day the cure was complete. The subject of the second observation was a workman who had been burnt on the foot by a quantity of concentrated sulphuric acid. The eschar left a deep ulcer, which defied treatment. M. Staes-Brame tried the continuous current in the same manner as before. After eleven applications of ten minutes each, the wound had completely cicatrised.

### REVIEWS AND NOTICES.

**LES CAUSES DE LA GRAVELLE ET DE LA PIERRE.** Par le Dr. DEBOUT L'ESTRÉES.

**DE L'URINE, ET DE SES ALTÉRATIONS PATHOLOGIQUES.** Par le Dr. GEORGE HARLEY, F.R.S. Traduit de l'Anglais par le Dr. F. L. HAHN. Paris. 1877.

MEDICAL works issuing from the pens of eminent French physicians and surgeons are, as a rule, well known to the profession on this side of the Channel; and it may be said that the works of Civiale and Leroy d'Etiolles on renal affections are as highly appreciated in Britain as they are in France. But, almost with the exception of these writers, little can be said to have been done by Frenchmen (in proportion to what has been done by Englishmen) since the days of the great Rayet, either in increasing our knowledge of the pathology, or of adding to our store of information in the therapeutics, of urinary affections.

True it is, that France has given to us a host of volumes on the treatment of kidney-disease; but they have emanated from the pens of medical advisers at mineral springs, and can scarcely be said to embody much new scientific matter. The work which we are now about to review is also from the pen of a medical man attached to a mineral spring. It consists of 135 pages, and, without being in the least degree pretentious, gives a very fair *résumé* of the pathology of gravel and stone from a French point of view.

Although we dare not venture to say that it contains anything either very startling or novel, yet its author has made a judicious use of the literature on the subject, and placed the data he has collected before his readers in a pleasing and instructive form.

In speaking of uric acid gravel and calculi, he says that he finds that the majority of cases come from towns; indeed, so large a proportion as 75 per cent. come from towns; and, as is observed elsewhere, by far the majority of the sufferers are men.

In 1,028 cases he met with at Contrexéville, 822 were men, 197 women, and 9 children from one to thirteen years of age. Moreover, while the average age of the females was forty, that of the males he reckoned at fifty years.

The probable cause of the disease he noted in 583 cases, and the result was that in 191 it was hereditary; in 160 the cause was indigestion; in 101, overfeeding; in 95, deficient exercise; in 35, violent moral emotion; and in 1, contusion of the kidneys.

The author is a partisan of Liebig's theory, that an excess of uric acid in the animal economy is due to an insufficient oxidation of the protein elements of the blood; and hot climates, he thinks, favour the oxidation process, and prevent the occurrence of uric acid gravel and calculi.

As regards oxalate of lime, he makes the very just remark that it more often appears in the form of calculi than of gravel, which is exactly the reverse of uric acid. He also mentions that, while uric acid is most common among the inhabitants of towns, oxaluria is most frequently met with in persons living in country districts. The proportion of males affected with the diathesis, too, is in vast excess of females; being, according to him, in the proportion of seven women to forty men.

Oxalate of lime calculi would appear, from his data, to be very common in France. In 1,252 calculi (1,000 analysed by Bouhardt, and 252 by Leroy d'Étiolles), 176 were noted as being composed of pure oxalate of lime, which is a considerable proportion when we recollect that oxalate of lime forms also the nucleus of many other kinds of calculi.

Our author adopts the view that an excess of oxalate of lime in the urinary secretion is due to an arrest in the oxidation of oxalic acid in the system. If properly oxidised, it would be thrown off by the lungs in the shape of carbonic acid. Oxalate of lime is frequently the concomitant of an excess of uric acid in the urine; and he attributes both their origins to much the same series of causes. He seems also to have adopted the idea, first thrown out in Germany, that the moral feelings have a great influence over the body in producing oxaluria; joy diminishing, sorrow increasing, the amount of oxalate of lime deposited in the urine.

As regards the treatment of oxaluria, he recommends the employment of alkaline mineral waters, and especially the calcareous variety, which he deems far preferable to alkaline soda waters. Of course, as might be expected from a man placed in his position, he thinks the waters of Contrexéville undeniably useful ("de l'incontestable utilité").

With reference to phosphatic calculi, the author thinks that they may be said to be due to an excess of elimination over formation; that is to say, while only the normal quantity gets into the body, an abnormal amount is eliminated with the urine, or, as he graphically expresses it, "*excès de dépenses sur les recettes*". One of the most potent causes of phosphatic calculi is the breathing of a vitiated atmosphere; as an example of this, he cites the case of a cook, who, he thinks, got the disease from inhaling carbonic oxide gas from the stove. Pthisis he also notes as an exciting cause, from its effect in inducing what he terms "*dénutrition*".

Another exciting cause of the formation of phosphatic calculi he assigns to be due to the well known ammoniacal fermentation of urea in the urine before its elimination from the bladder, a theory so well known in England that it need not be here further alluded to. To a fourth cause he alludes, which has been strongly pointed out by the author of the second book at the head of this article (one which mineral water doctors are rarely in the habit of alluding to), namely, the improper use of alkaline mineral waters, more especially, as he says, such as those of Vichy, Vals, and Carlsbad. As these often increase the tendency to stone, it would be well if some of our strong advocates for the use of mineral waters in calculous disorders paid attention to this hint, as it might probably reduce the number of sufferers from calculi in this country.

To aid the passage of small calculi, he advises dilatation of the urethra, especially of the orifice, where, from the normal construction of the part, a stone of some little size often becomes impacted. He also gives drawings of three kinds of urethral pincers that may, with advantage, be employed in extracting stones from the urethra of the male subject—namely, the *curette* of Leroy d'Étiolles, Hunter's pincers, and another which is called the urethral pincers, with a ring.

As regards the second work at the head of our article (Dr. GEORGE HARLEY'S), we need say nothing beyond that it is a very fair translation of the original, and does credit to the publisher for the way in

which the text and the woodcuts are got up. The contents of the book itself are so well known and appreciated by the reading part of the profession, both here and in America (where it was reprinted as soon as it was published in this country), that it would be quite superfluous for us to make any remarks upon it.

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS. By ROBERTS BARTHOLOW, M.A., M.D., Professor of Medicine in the Ohio Medical College, Cincinnati. Pp. 540. New York: Appleton. 1877.

ALTHOUGH many volumes have been written upon the above subjects, the excellent treatise before us really "presents", as the author states, "some new features of importance", and really deserves a special place amongst the best manuals that we have. We say this, not only after reading every page of the book, but after working with it for several months, and testing it by many comparisons of references. It represents extensive reading in American, English, and continental literature, and this not unduly paraded nor drily quoted, but well digested and condensed; it contains also much original work and observation, as we should expect from Dr. BARTHOLOW's reputation in connection with American prize essays on quinine, atropia, bromine, hypodermic medication, etc. At the same time, it is throughout very practical, including in its text an unusual number of useful formulae and ingenious suggestions, some empirical, but all, when possible, referred to physiological and scientific foundations.

As regards classification, many excellent modern text-books are purposely planned without one. Waring is alphabetical; Garrod mainly alphabetical and botanical (after De Candolle); Buchheim and Ringer mainly chemical; Phillips (vol. i) follows natural orders; Gubler, the French codex. The plan devised by Rabuteau we have long thought the best; and it seems to have partly suggested Dr. Bartholow's, which is scarcely an improvement upon it.

He makes four orders: 1. Promoters of constructive metamorphosis; 2. Promoters of destructive metamorphosis; 3. Modifiers of nerve-function (excitators and depressors of cerebral and spinal); 4. Evacuants. These are followed by another division of "topical remedies", antiseptics, counterirritants, etc.\*

We concede the merit of simplicity as claimed by our author, and the objections of repetition and confusion are fairly avoided. He does not attempt, after Neligan's failure, to place every drug in all its places; and could doubtless defend his position of phosphorus and arsenic amongst reconstructives (instead of neurotics), and of oxygen and carbonic acid amongst "topical remedies".

A good index is a sufficient guide; but it should be specially good. The present one does not name oxygen at all; nor boric acid; nor several other articles (etc.); though all well treated in the text. Sulphur, which occurs twice, has only its minor reference. Cisticifuga might be named also as actæa, etc.

The early pages deal succinctly with the *modus by which remedies are introduced into the system*. We note a caution as to the risk of damage to the middle ear from an injudicious nasal douche, minute as to inhalations and injections, and an account of transfusion. Gesellus' views as to the suitability of lamb's blood, and Aveling's instrument, are commended. Dr. Roussel will doubtless meet his meed in the next edition.

The systematic part commences with good chapters on *alimentation*, including analyses of foods and accounts of special diets—Bantingism, dry and milk diet, grape-cure and koumiss, and recipes from egg-nog to nutrient enemata with glycerole of pepsine. A formula for a cold meat essence might usefully be added; for chopped lean meat soaked for three hours in acidified water yields most of its albumen in a soluble form, which mixes well with Burgundy, etc.

Hydrotherapy is well discussed, including water packs, douche, etc.; but more might be said for the Turkish bath, and its value in mental disease especially.

If we are reminded of Rabuteau in the classification, we seem to trace Gubler in the arrangement under each substance—certainly excellent models. We have 1) the English, Latin, French, and German synonyms; 2) a "definition", and a list of preparations; (3) then "antagonists" and "incompatibles"; (4) "synergisms" (Gubler's "syner-

\* Dr. Rabuteau's classes are—1. Modifiers of nutrition; 2. Of innervation; 3. Of innervation and muscular power (*myostiltes*); 4. Of muscular power; 5. Of secretion and excretion; 6. Eliminants; 7. Topical remedies; 8. Antiseptics. But special ability is shown in the subdivisions of these—e.g., in Class 1: a. Stimulants of nutrition; of hæmatosis, as oxygen, iron, hypophosphates, coca; b. Moderators of nutrition—alcohols, coffees, iodides, arsenicals, alkalis, etc.; c. Repairers—analectics, milk, lime phosphate; d. Euphetics—pepsine, hydrochloric ac. d. etc. (*Éléments de Thérapeutique*, 2nd edition, 1875). We may append Huxham's remark: "Auch die Gruppierung bleibt immer, wie das System, ein Kind ihrer Zeit" (*Hanbuch*, 1874).

giques" and "auxiliaires"); (5) "physiological effects"; (6) "therapy"; and, at the close, exact references to original sources that have been consulted.

The specialty of the book lies mainly in these latter sections. They include little or no history or theory or quotation, but an interesting and practical *précis*, mainly of modern work and personal experience. They are not cast in one mould, nor do the observations follow a definite order (*e.g.*, of systems, nervous, circulatory, etc.) Brevity and perhaps interest are gained by this; but the longer articles (*e.g.*, mercury) are not free from some confusion. In the therapeutical sections, fresh subjects are indicated by italics only.

Hypodermic medication receives ample illustration; and Dr. Bartholow claims priority in the use of *dép* injections (p. 323). Thus, in chronic neuralgia, he injects from five to fifteen minims of pure chloroform deeply into the affected part, causing pain and swelling, but often curing. He claims, too, the prevention of unpleasant cerebral effects from opium by potassic bromide; and, whilst acknowledging fully Dr. Fraser's researches on physostigma (1869), quotes his own experiments of 1867, which first illustrated the antagonism between that drug and atropia; and reminds us that he was the first to indicate the value of atropia in the night-sweats of phthisis. (He suggests one-sixtieth of a grain, but we have found half that quantity sufficient.)

Some of the therapeutical dicta should, we think, be qualified. Few can concede that alum is the most effective agent for the cure of colica pictorum. The experience which finds hydrocele and liver-hydatis *invariably* cured by galvano-puncture must be unique. To say that exophthalmic goitre is cured by galvanisation of the sympathetic, vagus, eyes, and thyroid, implies the completion of observations as yet little more than commenced; and that "ether-spray alone suffices to effect a cure in chorea" has never been verified within our practice or observation, both fairly large as to this point.

The author's plan of citing authorities at the end of each section (as in the *Nouveau Dictionnaire de Médecine*) is very good. One must not expect to find the older writers; but the list of good modern names in treatises, monographs, and periodicals is remarkably full. If criticism were directed at all in this direction, one might note, though with every allowance, omissions sometimes of references to names quoted in the text (*e.g.*, Höbner and Schimpf, under Phosphorus); or omissions of some recognised monographs, as Fleming on *Aconite*, or the older Groenfeld, who fought so well for cantharides and its antidote camphor; or the use of past, instead of present and amended, editions (*e.g.*, Gubler, 1868, instead of 1874; Trousseau, 1868; Ringer, third edition, etc.).

We proceed to note, in the order of the volume, some details calculated to prove of interest. Under pepsine, Scheffer's process and Beale's only are accepted; Morison's and Bullock's, the *essence* of O. Liebreich, and the diastase preparations of Chassaing, do not seem sufficiently appreciated in the United States. Ronth fairly deserves mention for success in treating malignant uterine growths by pepsine. We have seen good cases. A formula with lactic acid (glyc. pepsine 5xij; acidi lactici 3iv) is commended in the aepsia of infants, and in the slow irritative dyspepsia of adults. As to the use of the acid in diabetes, the originator of this (Cantani) is not quoted. Dr. B. W. Foster's cases of improvement are referred to, but not his observations as to the production of rheumatism by the acid. These are very clear, but were verified only in certain diabetics.

Oils and fats are grouped together. Cod-liver oil is commended in fibroid lung and chronic tuberculosis, not in caseous pneumonia or acute phthisis; the same remark is made as to hypophosphites. In atheroma it is commended. Good formulae are given for its administration: *e.g.*, that of Paresc, a mixture with charcoal and coffee digested and filtered; also with chloroform, with eucalyptus, and with spirits of lavender and brandy, or saponified with lime as by Van der Court.

The list of iron preparations includes Monsell's solution of sub-sulphate (noted for its astringency without causticity), iron "alum", lactate, oxalate and malate, a syrup with manganese, etc.; but we should have been glad to see Rabuteau's protochloride, with some estimate of its value, and of that of newer preparations—the dialysed, the colloid, etc., and the granular effervescent forms. Creuse's chloride and the pyrophosphates are recommended. A novel combination for constitutional syphilis is iodoform ʒj; hydrargyri chloridi corrosivi gr. j; ferri redacti ʒj. Fiant pilule xx. Tincture of the chloride of iron is considered most serviceable in the prophylaxis and treatment of acute rheumatism when occurring in the pale, delicate, and cachectic; but its value in erysipelas and diphtheria is questioned. It can act only as a tonic, not as a specific.

"When a course of arsenic is begun, large doses should be prescribed, and the quantity regularly reduced; thus chronic poisoning is

avoided." It may be so, but only at the risk of acute poisoning. We cannot think the direction safe, knowing from experience that one minim of liquor arsenicalis will cause in some intense general lichen, in others choleraic diarrhoea. The "synergists" of arsenic are set down as all substances which promote constructive metamorphosis; but we should add antimony, quinine, ergot, bromides. In the text, antimony is widely separated from arsenic as an agent *increasing waste*, and the excretion of carbonic acid and urea. Ackerman came to this conclusion; but we cannot consider it yet proved. Arsenic cannot be said to produce a true psoriasis, nor is it quite correct that "the more chronic the malady the more suitable the drug is".

The statement that arsenic causes *albuminuria* in prolonged doses rests, we believe, upon only two cases (Dr. W. Mitchell), and cannot be stated in general terms. The value of the medicine is fully recognised by Dr. Bartholow in irritative dyspepsia, vomiting, diarrhoea, amenorrhoea, cerebral congestion, and chronic arthritis. Its use is said to hinder a bromic eruption.

A notice of aromatic bitters includes *serpentaria*, Virginian prune, eucalyptus, hydrastis, and the cinchonas. As regards the use of the wild cherry in heart-disease, its peculiar combination of a sedative (prussic acid), with aromatic tonic principles, indicate it in irritable conditions of the heart as well as in phthisis and bronchitis (Clifford Allbutt). *Eucalyptus* stimulates the secretions and quickens the circulation at the same time that it lowers tension. It is recommended in debility, gastric and bronchial, renal and vesical catarrh, in hysteria, and climacteric flatulence, etc. *Hydrastis* possesses similar properties, with some of those of quinine in addition. It is valuable in different forms of catarrh, and of ulceration and congestion of mucous membranes, in pharyngitis and coryza, gastric and intestinal catarrh, anal fissure, leucorrhoea, gonorrhoea, etc.; and it is only second to quinine in intermittents. We hope to see these two remedies in our own *Pharmacopœia*.

Concerning *quinine*, Dr. Bartholow concludes that it lessens the excretion of uric acid, but not that of urea. It diffuses rapidly, but is eliminated slowly, and its maximum effect is obtained in about five hours; hence he advises a full dose (ten grains) at that period of time before a paroxysm, and also during the sweating stage. Its value in neuralgia he restricts to anæmic cases.

The sulphites he does not credit with any value in septic diseases; but we think that sulphurous acid, from the cases of Hjaltelin, Polli, A. W. Foot, and others, has a fairly established virtue in small-pox and typhoid fever.

It is said that in empyema undiluted tincture of iodine may be injected without risk. No limit of quantity is mentioned, but we have reason to know that consequent iodism may be very serious in character. We can agree, however, with the strength of one to fifteen, though that is not generally adopted.

*Iodo-tannin* is a saturated solution of tannin in tincture of iodine, or may be prepared by dissolving one drachm of iodine with one ounce of tannic acid in one pint of water; filtering and evaporating to four ounces, or extemporaneously with mixture of galls and of iodine. These are very useful in chronic uterine inflammation. A decolorised tincture of iodine may be prepared with hyposulphite of sodium and spirits of ammonia.

Of *gold*, the chloride is a local caustic and an irritant poison. Small doses of the double chloride with soda are recommended in nervous and irritative dyspepsia, chronic syphilis, amenorrhoea, sterility, and in cases opposite to those benefited by bromides, including cerebral anæmia. Dr. Bartholow specially values them in chronic Bright's disease and in melancholia.

In the account of *copper poisoning*, a purplish line along the gums is still described in accordance probably with some doubtful cases of Sir D. Corrigan. A bluish or greenish line on the teeth would be a more accurate description according to Clapton, Bailly, and others, who are worthy of reference on this matter (*Clinical Society's Transactions*, vol. iii, and *Union Médicale*, 1874).

In the group of substances containing tannic acid, we have geranium and rubus, hamamelis and castanea; but without much information. *Stillingia*, *sanguinaria*, and *xanthoxylum* are classed with our *guaiacum* and *colchicum*. The former is a valuable "alterative", and markedly stimulates the secretions; it is recommended in constipation and in early cirrhosis, in scrofula, and chronic syphilis.\*

Electricity is well and fully treated; strychnia and ergot also, with special chapters on their hypodermic use. One-fortieth of a grain is the suggested dose of the former, without reference to Barwell's larger doses. Ergot is commended in varicocele, and in "enlargement

\* The specially American remedies are now more accessible to us than formerly. Messrs. Ferris showed at Manchester an excellent case of the "extracts", which are prepared with glycerine and spirits, and are more concentrated than our tinctures.

of the dorsal vein of the penis" "it may cause tonic contraction of the sphincter vesicæ".

Amongst contraindications for *chloroform*, thoracic effusions should be included. The risks of *incomplete* anaesthesia are recognised, and Nélaton's treatment by inversion recommended. Chloral can only relieve *pain* "by suspension of cerebral function", i. e., in dangerous doses. As an anodyne, therefore, it should be prescribed together form a clear solution often of great service locally in neuralgia." Hypodermic morphia enables us to dispense with some chloroform, and is therefore advisable as a preliminary to inhalation. The observations of Scanzoni and Loomis, as to morphia injections controlling *uræmic convulsions*, are supported. The effects of morphia are said to be heightened by conia; and the manner in which they are modified and partly antagonised by atropia is fully discussed. Not more than three doses of one-twentieth of a grain, at intervals of fifteen minutes, are advised as antidotal.

*Gelsemium* is placed between conium and arnica. It is recommended in meningitis, pneumonia, dysmenorrhœa, neuralgia, etc.

Under *carbolic acid*, we have an account of the successful "parenchymatous or deep-seated injection" of a two per cent. solution in erysipelas, pleuropneumonia, and intermittents, as well as in lupus, synovitis, etc.

Acupuncture and aquapuncture and "Baunscheidtismus" (with many needles) meet with notice.

Finally, we would remark that verbal and typographical faults are few, nor are Americanisms noticeable; "marvelous" we observed, and "latter" misplaced for "former" (p. 259), and "ill-continued" for "ill-conditioned"? (p. 157); and we fancy that "variolus-like" is scarcely correct, and that "opinions have been emitted" has a curious sound.

But now we think enough has been said to discharge the duty of an impartial and appreciative critic, to illustrate our introductory praise of the book, and to make our readers welcome it as a really valuable addition to modern literature.

#### SOME COMPLICATIONS OF EPILEPSY AND HYSTERO-EPILEPSY. By Dr. EMILIE BOVILL. Paris: 1877.

WE congratulate Dr. EMILIE BOVILL on having produced a succinct and very interesting monograph, calling attention to some of the complications of epilepsy and hystero-epilepsy. A large collection of observations by various authors is well arranged, attention is carefully directed to the points taught by each case, and conclusions are fairly drawn from the clinical and physiological facts. The concomitants of epilepsy here dwelt upon are phenomena of the congestive order, such as alterations in the character and amount of the urine, congestions, and ecchymoses of the skin and other parts, elevation of the temperature, etc.

The first chapter is a *résumé* of the observations of various authors of the secondary congestions following organic lesions of the brain or spinal cord, resulting from traumatic or morbid lesions, produced experimentally or secondarily to convulsive attacks. It is well known that polyuria, glycosuria, and albuminuria of a temporary character may follow cerebral lesions; but there are differences of opinion as to the mechanism by which this is brought about. In proof that in many cases it is produced by a vaso-motor disturbance, the author cites well observed instances in which localised congestions or ecchymoses have been found in the skin and in the internal organs after death, at the same time laying much stress on the congested state of the optic papilla during epileptic fits, as observed by Dr. Hughlings Jackson and other physicians.

The view that these congestions and ecchymoses are usually produced by asphyxia resulting from the tonic spasm of the respiratory muscles during the fit, is combated on the ground that in some of the cases quoted congestion of the ear, nose, and other parts preceded the fit, and, therefore, could not be necessarily due to muscular spasm. M. Vulpian likewise admits the important part which the vaso-motor nerves play in the production of congestive phenomena in connection with epilepsy. If the possibility of a congestion of organs be admitted as a part of the essential phenomena of epilepsy, it is easy to see how an alteration in the urine may result, when we consider the effects of physiological irritation of various parts of the medulla oblongata in producing polyuria, albuminuria, and glycosuria. As to the causation of the high temperature sometimes met with during convulsive epileptic attacks, two views are current, tonic muscular spasm is usually considered to be the cause, but some physiologists consider it as a purely vaso-motor phenomenon, and to this view Dr. Bovill inclines. Arguments in favour of the vaso-motor theory are that violent muscular exertion cannot elevate the temperature of the body more than .5 deg.

cent. to .4 deg. cent. (1.8 deg. to 2.2 deg. Fahr.); whereas in epileptic fits it may rise to 40 deg. cent. (104 deg. Fahr.); further, although in hystero-epilepsy there is much muscular spasm, the temperature does not rise above 38 deg. cent. (100.4 deg. Fahr.). We doubt ourselves if any form of hysterical muscular contraction represents as great an expenditure of force as the prolonged general tonic spasm of epilepsy. In further support of the theory advanced, Dr. Bovill refers to the constant dilatation of the pupils and acceleration of the pulse during the attacks, also strongly insisting on the analogy of those functional conditions with similar results proceeding from known organic lesions of the nervous centres.

## NOTES ON BOOKS.

THE volumes of ZIEMSEN'S *Cyclopædia of Medicine* continue to appear with commendable promptitude. Volume xvi, which reached us lately, contains a series of treatises on Diseases of the Locomotive Apparatus and General Anomalies of Nutrition, by Dr. H. Senator of Berlin, Professor P. Seitz of Giessen, Professor H. Immermann of Basel, Dr. Birch-Hirschfeld of Dresden; translated by Dr. E. Buchanan Baxter of London, Dr. John Todhunter of Dublin, Dr. Godfrey Argner and Dr. Frank B. Foster of New York, and Dr. Henry P. Bowditch of Boston. This volume fully maintains the deservedly high reputation which has been acquired by its predecessors. The publishers inform us that in the progress of the work it has been necessary to make some addition to the number of volumes. Looking to the completeness and value of the monographs, and the extent of subjects treated, this may readily be understood; and the subscribers will readily acquiesce in modifications dictated by scientific considerations and wholly in the interest of the completeness of the *Cyclopædia*.

*Iconographie Photographique.* La Salpêtrière (Service de M. Charcot). Par BOURNEVILLE et REGNARD.—The service of La Salpêtrière is extremely rich in eccentric and strongly marked types of nervous disease, especially of hysteria and hystero-epilepsy. Cases of this kind, which are all of a chronic and troublesome character, and require to be received in asylums, where they can be retained under observation for years, do not always receive the accurate scientific attention which they have had at the hands of M. Charcot. M. Bourneville, now the able editor of the *Progrès Médical*, was for some years *interne* in the service of the Salpêtrière, and has since continued to watch the wards with unabated interest. In these photographs are to be found the reliable and permanent records of some cases of singular interest, especially of those in which the attitudes adopted during hystero-epileptic attacks are most striking, and have a certain historical and religious as well as scientific interest. Among them are cases of "cataleptic crucifixion", such as those to which a peculiar religious signification has been given by the cases of Louise Lateau and others. The whole series of plates thus far published, illustrating various phases of hystero-epilepsy, are singularly interesting, and will certainly be welcomed by neurologists as a valuable contribution to the phases of disease very liable to misinterpretation, and which can only occasionally be thoroughly studied. Each part contains four photographs, and is published at three francs, at the offices of the *Progrès Médical*, 6, Rue des Écoles, Paris.

*New London Flora*, by E. DE CRESPIGNY, M.D. (Hardwicke and Boyce, 1877) is an extremely handy little guide for young botanists to the flora of the home counties. It is evidently the result of many years of botanical field-work; it can be carried easily in the pocket, and gives at a glance for each locality a view of the plants to be looked for. It extends to districts within easy reach of London, and is a very valuable companion for botanical excursions for young metropolitan botanists. The section which relates to cryptogamic plants is not so well done as that of the flowering plants; but, taken as a whole, the book is one which is highly creditable to Dr. De Crespigny, and will be very useful to the class whom it addresses.

*Fistula in Ano, a Double Case, one treated by Knife, and the other by the Elastic Ligature*, by C. F. MAUNDER, is the title of a pamphlet consisting of a report of a case of a length equivalent to less than a page of this JOURNAL, reprinted from the *Clinical Society's Transactions* for 1875. Prefixed to it is a list of a dozen "Contributions to Surgery by the Author", the second item of which runs thus:

"TUMOUR OF LARGE PORTIONS OF LOWER JAW REMOVED WITHOUT EXTERNAL WOUND. FIVE WOODCUTS. 2s."

[The practice of our art will have one horror less for a patient who can be assured that no unsightly scar will disfigure his face.] The "pamphlet" is priced at one shilling.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 5TH, 1878.

HELMHOLTZ AND VIRCHOW ON MEDICAL  
RESEARCH.\*

A NOTICE of the opinions lately expressed on some important questions, both of the past and present, by two of the most distinguished scientific men in Germany cannot fail, we think, to interest the readers of the BRITISH MEDICAL JOURNAL. Professor Helmholtz has recently published his address on "Thinking in Medicine", delivered at the anniversary of the establishment of the Military Medical School in Berlin; and Professor Virchow has also, by issuing it in a separate form, given a wider circulation to his speech "On the Freedom of Science in Modern States", made in reply to Professor Haeckel, at the Munich meeting of German naturalists and physicians.

Although best known to us as a natural philosopher, Helmholtz originally studied medicine, and was for some time Professor of Pathology at Königsberg; and he gracefully acknowledges his own indebtedness to his early pursuits, as a preparation for the work of his later years. His essay is a vigorous denunciation of *a priori* conclusions, and an enforcement of the rule that doctrines must stand upon their tested and proved merits. This is maintained from a survey of the history of medicine, from the days of Hippocrates downwards. The fundamental error of the ancients was, he says, that they pursued a false ideal of scientific study, owing to their overestimate of the deductive method. The bad effects of this told with especial force on the progress of medicine. The lofty standard of Hippocrates was gradually lowered; a vague psychology took the place of observation; theories were formed irrespective of the opposition of Nature; the more rigid the system, the fewer became the proceedings of medical art; and with the lapse of centuries, the more the schools found themselves threatened by the advance of real knowledge, so much the more did they rely upon the authority of the ancients, and so much the more intolerant did they become to innovation. Thus it was that Vesalius was summoned before the theological faculty of Salamanca; that Servetus and his book were burned at Geneva; and that the Paris faculty forbade the teaching in their lecture-rooms of Harvey's discovery of the circulation. And so one system rose after another, each, perhaps, possessing some element of truth, but faulty from its exclusiveness; for, from the false logic in vogue, it was believed that upon one theory a complete body of doctrine could be founded. At one time, the humoralist pathology prevailed; at another, the solidist.

But coming to a more recent period, what was the state of medicine at the close of the first quarter of the present century? To the vitalist physician of that day, it did not seem that the important part of the processes taking place in the human body was the result of natural powers, acting from necessity and law. This was deemed of secondary moment, and hardly worth a careful study. Of this, Helmholtz gives some curious instances. It was the time when auscultation and percussion of the organs in the chest was being introduced into the clinical wards of the Berlin Hospital, but they were decried as coarse mechanical modes of investigation which a man of penetration did

not require, and which also degraded the patient by treating him as a machine. Even counting the pulse by the aid of a seconds-watch was regarded by some old gentlemen as not in good taste. As regards the ophthalmoscope, a very distinguished surgeon refused to employ it, saying that it was dangerous to allow bright light to fall upon a diseased eye; and another declared that the mirror might be useful for surgeons with bad eyes, but that he had good sight and did not require it. A distinguished professor of physiology of that day had a discussion with his colleague, the professor of natural philosophy, on the formation of images in the eye, and was invited by him to witness an experiment. He rudely declined the offer, saying that "a physiologist had nothing to do with experiments". At present, it appears hardly credible that such opinions could have been entertained at so recent a period, but marvellous indeed has been the progress of medical science during the last forty years. In Germany, an enthusiastic impulse to sound work was given by the example and teaching of John Müller, the physiologist, who, although theoretically a vitalist, was essentially and firmly a natural philosopher. To him, all opinions were but hypotheses which must be brought to the test of facts and decided by them alone. His spirit strongly animated his pupils, among whom may be numbered many well-known scientific men of the present day.

Again and again, does Helmholtz warn us against being seduced into mere speculation, unproved and unconfirmed, the literature of which he characterises as worthless for the interests of science. But, whilst condemning the making of empty hypotheses, he guards himself against the supposition that he wishes to depreciate genuine original thought; it is the pretension of the sciolist which is so offensive to him. For the finder of superficial resemblances, which are at once proclaimed as discoveries, with jealous maintenance of the rights of priority, he has no feeling but contempt. The medical inquirer, who has to do with the weal-or-woe-bringing powers of nature, has the duty, under heavy responsibility, of seeking the truth, irrespective of consequences; he should be able to foretell the result of any given proceeding. But to gain this power, there is no other method than by careful and repeated observations, by experiment and induction, to search for laws; and when found, further study is required to ascertain under what circumstances and within what limits they operate. This is an unceasing labour.

For metaphysical systems, also, Helmholtz has no love, believing that they hold the same relation to true philosophy which astrology held to astronomy. He even goes so far as to say that every metaphysical inference is either a fallacy or a disguised empirical conclusion. And in confirmation of his estimate, he quotes Socrates and Kant, who each declared all propounded systems to be empty and deceptive.

We have said sufficient to show that the whole address is a protest against premature conclusions and precipitate generalisations; and the lesson may be useful to us in this country. It is to be feared that much of our work is incomplete and will prove unstable. How many incorrect observations and unsound inferences have we not to deplore! How much more valuable would many of our medical works have been had they, prior to publication, received the testing and proving which Helmholtz so strongly advocates!

Professor Virchow's speech will be read with pleasure by those who are familiar with German, and who watch with attention the changes which science and its exposition are undergoing. It is a model of clear and cogent reasoning, clothed in bright and sparkling language. As is known to the readers of his "History of Creation", Professor Haeckel of Jena is one of the most devoted followers of Darwin. At the recent congress at Munich, he urged the propriety of the teaching in schools, as an established doctrine, of his theory of descent and development. We give a short summary of the answer which his argument called forth.

Virchow commences by contrasting the liberty of speech at present enjoyed in Germany with the restrictions on its freedom half a century

\* *Das Denken in der Medicin.* Rede gehalten, u.s.w., von Dr. H. Helmholtz. Berlin: 1877.—*Die Freiheit der Wissenschaft im modernen Staat.* Rede gehalten, u.s.w., von Rudolf Virchow. Berlin: 1877.

ago; but not feeling assured as to the permanence of the boon, he enforces the need of caution, moderation, and a certain self-restraint in the expression of opinion, so as to avoid offence. He thinks that the line between the merely speculative region of science and actually acquired territory should be clearly indicated. For firmly established scientific truth, we may fairly ask its full acceptance by the public. However opposed to previous notions, and whatever difficulties may attend its promulgation, when we are fully convinced of the truth of a doctrine, we must not hesitate to communicate it to the world. And here, parenthetically, he energetically defends scientific men against the charge sometimes brought against them of half-knowledge. How can their knowledge be otherwise than imperfect? The field of science is so vast that a cultivator can occupy but a very small part. What we should aim at, is to be clear as to the principles of science and thoroughly acquainted with our deficiencies. The slow and oscillating advance of positive knowledge is well illustrated by the history of the belief that diseases depend upon a *contagium animatum*. Although it arose in the sixteenth century, it was not until the nineteenth that any actual confirmation was brought forward; and whilst it has been proved as regards some diseases, and is probable as regards others, caution requires us to exercise reserve in its complete acceptance.

Professor Virchow then addresses himself to the question of development, and strongly lays down the rule that propositions must be limited to the subjects respecting which they have been substantiated. He fully admits the seductive character of the theory which embraces the whole of living forms, from the lowest protista up to man, and links them with the inorganic world. It responds to that spirit of generalisation which has existed from the earliest antiquity. It is easy to say that a combination of carbon, hydrogen, oxygen, and nitrogen (the firm of Carbon and Co. Virchow facetiously names it), endowed with a peculiar influence, creates a form-unit or plastid; and also that the spirit which animates this is the result of the sum of the powers which the chemical atoms possess. This may be so; but before it can be taught as doctrine, a long course of careful investigation is needed; and it must be emphatically stated, that all actual knowledge respecting the processes of life is opposed to any such supposition. Proof is wanted that inorganic matter has ever developed into organic; and as to the connection of the two worlds, we must simply acknowledge that, in fact, we know nothing; and there is no middle course between admitting the existence of equivocal generation and that of a Creator. Thus, as nothing has more hindered the progress of natural science, in the estimation of the world, than premature synthesis, it is especially desirable that we resist the temptation to put prominently forward mere speculation.

Our space will not allow us to follow Dr. Virchow in his parallel between theological and scientific teaching, but we give an outline of it. In each, the same elements exist; in each, we have a stream of dogma as well as of subjective and objective doctrine. Our grand aim should be to diminish the first and strengthen the last—that which deals with realities and facts. In medicine, the merely subjective part is still unduly cultivated; so much so, that probably one-half of our medical literature might be suppressed, without prejudice to our real knowledge.

The argument upon development, and the relation of man to other animals, is carried into palæontology, and the conclusion is gained, that every step in prehistoric anthropology leads us further from proof of the doctrine of descent. There is no fossil type of a lower human grade. The grand lesson which is inculcated is this: in all that is delivered to the public, whether by writing or speaking, double care should be taken to mark clearly the distinction between what is objectively true, and what is merely an inference or a conclusion from analogy. If knowledge be power, it is that of facts, not problem or speculation. As writers and teachers, we misuse our power, and jeopardise its permanence, unless we keep upon this unassailable ground.

Our readers cannot fail to be struck by the identity of spirit per-

vading the two discourses which we have brought under their notice. We may augur well for the progress of science, both medical and general, when its cultivators are thus animated.

#### POST MORTEM EXAMINATIONS FOR ACCIDENT INSURANCE COMPANIES.

SCARCELY a week passes in which we have not to record some irregularity in reference to *post mortem* examinations for medico-legal purposes. At one time, a coroner, uncertain about the necessity for holding an inquest in a particular case, invites a medical man to make a *post mortem* examination, without sending the usual warrant or order, as directed by the Medical Witnesses' Act. As nothing was found in the dead body to account for death from causes other than natural, a report was sent to this effect. The coroner declined holding an inquest; and, as no inquest was held, he refused to pay the usual fee. Here the services of a medical man were utilised by a coroner to enable him to determine whether the case was such as to require a formal inquest or not.

On another occasion, a coroner gave a general order to a medical man to make *post mortem* examinations in his district without waiting for the warrant required by the Act. He thus delegated to another a power which the law has conferred on him alone, of determining in what cases a *post mortem* examination should be made and an inquest held. This is really placing members of the profession in a very invidious position, as it is well known that a fee of two guineas is allowed for each *post mortem* examination, and it might be uncharitably suggested that medical men would thus be disposed to exercise this power in cases in which neither a *post mortem* examination nor an inquest was really required. We have had occasion to comment on a case of this kind lately, in which, on account of the irregularity, the magistrates disallowed the usual fee.

If we notice this case again, it is chiefly in consequence of the strange defence of this illegal act set up by the coroner. He states that, "since the magistrates had refused to allow the coroner's officer his travelling expenses, that functionary had to communicate with the coroner by post; consequently, in the case of death from volatile poison, all traces of it would be lost by the time a warrant arrived in that manner". Volatile poisons are not such a frequent cause of sudden death as to justify this conduct; and, when death has been thus caused, there will be no fear of the evidence being lost, even when communications in the district could only take place by post. The coroner is not justified by the Act in issuing such a general order; and a medical man should decline to accept it, as it not only throws on him an undue responsibility, but it exposes him to a charge of looking after his own pecuniary interest.

In a third case, which occurred during the last month, we find that a medical man, interested for an accident insurance company, anticipated an inquest, and performed a *post mortem* examination on the body of the deceased without the permission of the relatives or the authority of the coroner! The deceased was a moulder, and there was evidence that he had sustained some injury at his work on October 2nd. He continued to sink until December 13th, when he died from the consequences of the injury. His life was insured for one thousand pounds in an accident insurance company. The company's surgeon, probably with a view of procuring evidence that the man had died from some natural cause, did not wait for the coroner's inquest or a warrant for making a *post mortem* examination, which would most likely have been handed to another medical man not acting for the company. The coroner very properly had another examination of the body made for the inquest; and upon this evidence the jury returned a verdict of "Accidental death", with the request that a copy of the evidence and verdict should be forwarded to the Home Secretary, together with remarks to the effect that the mutilation of the body before they had seen it was a most improper proceeding, and one likely to be detrimental to the interests of justice when done by an insurance surgeon.

or any interested person. Insurance surgeons should beware of imitating this conduct. It is not only an indecent proceeding to make a *post mortem* examination of a body without the consent of the relatives of the deceased, but, if the coroner have already issued his precept for an inquest, it might subject the offender against decency to a committal for contempt of the coroner's court.

The facts on which we have here commented show that it is time some steps were taken, by a new enactment, to render such proceedings as these impossible.

#### THE WATER-SUPPLY OF MANCHESTER.

It is probably now unnecessary to enter upon an argument, in order to prove that it is undesirable needlessly to alter the natural condition of any part of the Lake District by the construction of extensive engineering works. On the other hand, general statements have been put forth which have produced an impression on the minds of many that, if access to the valley of Thirlmere be now denied to the corporation of Manchester, it will be impossible to provide for a large population the supply of water which is essential to their health and comfort.

It is therefore desirable to examine these general statements by the light of information derived from sources which cannot be disputed.

In the first place, as to the assertions themselves, Mr. Bateman, in his official reports, has informed his employers that the exhaustion of all nearer resources makes it needful to have recourse to some distant place for supplies. The sense in which he uses these words may be judged of by what is added; namely, that, under present circumstances, no source of supply which will not yield more than five or six millions of gallons per day would be worth considering: a quantity, nevertheless, equal to the total consumption for domestic and sanitary purposes in the city of Manchester, according to statements put forth on authority by the *Manchester Courier*.

Mr. Grave does not deny the existence of collecting grounds still unoccupied, but wishes to leave them to the other towns of Lancashire.

Then, as to the proportion between probable requirements and available supplies, we will quote from Mr. Bateman's reports, statements on authority issued through the Manchester papers, the report of the Royal Commission on Water-Supply, 1868, and the census returns of 1871.

We are informed, through the local papers (October 30th), that the corporation is now under statutory obligations to supply a district comprising an area of eighty-four square miles, with a population of 800,000, and that they do not desire to extend this area. The quantity of water now distributed is put down at 17,000,000 gallons daily; but, as the same figures were given for 1874, we will call it 18,000,000 gallons. This will give a supply of  $22\frac{1}{2}$  gallons per head to the 800,000. The population referred to may be divided into the inhabitants of Manchester, those of Salford, and those of the outlying townships. An examination of the last census returns shows that, if the rate of increase which prevailed in these several populations respectively from 1861 to 1871 be continued until 1897—twenty years hence—the number will stand at 1,125,000.

How are these people to be supplied? Mr. Bateman tells us that works existing or now in course of construction will supply 25,000,000 gallons daily. Then we find, from the report of the Royal Commission, that water obtained from deep wells sunk in the new red sandstone is in many respects, and for many purposes, to be preferred to any which can be got from surface-drainage. Almost the whole of Lancashire, and especially the neighbourhood of Manchester, is situated on this formation, and, from four wells very imperfectly sunk therein near Liverpool, 7,000,000 gallons per day are obtained. It would be very singular if, within an area of eighty-four square miles round Manchester, four wells equally productive cannot be sunk. This would

raise the supply to 32,000,000 gallons daily, and afford  $28\frac{1}{2}$  gallons per head to the supposed population of 1897, instead of  $22\frac{1}{2}$  gallons per head, the present quantity, of which the corporation has with good reason always boasted as liberal and unstinted.

The wants of the county of Lancaster are often put forward as a justification of the present application, and therefore it may be well to examine this question as closely as possible. The population of the whole county, including Liverpool, is something under 3,000,000. This is a large number; but the natural resources of the county are large also. The rainfall is much greater than that which prevails in most other parts of the country. The prevailing substratum of new red sandstone affords an unusually productive and valuable source of supply; and few counties of England possess within their own limits, or immediately contiguous, so large an extent of moorland-surface which is all available for collection, the only difficulty being the expense of constructing reservoirs in some localities. Under these circumstances, we find that one municipal body, nearly at the extreme south-east of the county, having already secured a supply of 25,000,000 gallons daily from sources entirely without the county limits (for such is the fact as respects the Longendale supplies), now seeks powers to construct works in Cumberland, a county separated from them by the whole length of Lancashire and thirty miles of Westmorland, and thus obtain the possession and control of a supply amounting to 75,000,000 gallons daily: a quantity fully equal in itself to the wants of the whole county, even if its natural resources were not greater than those of the Arabian Desert.

To infer from the above data that the corporation of Manchester can plead no pressing needs in justification of their demands, is surely not an unreasonable conclusion. Anyhow, there is time enough for a deliberate inquiry into all the important questions involved.

THE publication of the *Monthly Microscopical Journal* is, we hear, in future to be discontinued.

THE *British and Foreign Medico-Chirurgical Review* has also, we regret to say, become extinct, its tardy quarterly appearance being probably fatal to its interests.

THE *Quarterly Journal of Anatomy and Physiology* will henceforth, we hear, be altered in character, as Dr. Michael Foster and Dr. Rutherford, two of its editors, propose to issue a *Journal of Physiology* in a separate form.

THE monthly *London Medical Record* is to be permanently enlarged, in order to give adequately increased space to systematic abstracts of the immense and growing mass of foreign medical literature.

THE *Glasgow Medical Journal* is to be published in future in the monthly shape, under the editorship of Dr. Coats.

THE *Birmingham and Midland Counties Medical Review* has been entrusted to the able charge of Dr. Saundby as editor.

THE first number of *Brain*, a quarterly journal of neural pathology, edited by Drs. Bucknill, Crichton Browne, Hughlings Jackson, and Ferrier, will appear on April 1st.

THE *Australian Practitioner*, a new quarterly journal of the medical sciences, reaches us from Melbourne. It promises to be the most creditable medical journal which has yet been issued in the Australian colonies.

WE much regret to record the death of Dr. R. Payne Cotton, in the prime of life, from dilatation of the heart. Dr. Cotton's contributions to the clinical study of chest-diseases have been of much practical interest.

THE Association medallists will dine with the Committee of Council and their friends at the Grosvenor Gallery Restaurant on Wednesday next, January 9th.

#### THE NEW SYDENHAM SOCIETY.

AFTER many delays, we are glad to hear that the first part of the Society's revised edition of Mayne's *Lexicon* is likely soon to appear. Mr. Henry Power and Dr. Sedgwick are its joint editors. It will, we believe, be much enlarged and wholly remodelled.

#### MEDICAL SOCIETY OF LONDON.

ON Monday next, the first of the Lettsomian Lectures at the Medical Society of London will be delivered by Mr. Francis Mason, Surgeon to St. Thomas's Hospital. The subject will be Diseases of the Face. On Monday, January 14th, Dr. Foulis of Glasgow will read a paper on Excision of the Larynx, and will show the patient upon whom he has lately performed the operation. The artificial larynx manufactured to replace the natural one will be exhibited, together with the various reeds which produce the voice. By means of a König's revolving mirror, the sound-waves will be demonstrated.

#### A DOCTOR'S WINDFALL.

THE Aberlour succession case, of which we gave an outline a few months ago, came on for trial in the Edinburgh Court of Session last week, and was finally closed by compromise. The pursuer, Mrs. Yeatman, *née* Temple (who jilted her friend Miss Macpherson Grant, to whom she was solemnly pledged to live single until death should them part), agreed to accept £10,000, and withdraw all claims henceforth and for ever. Miss Grant, never forgiving the defection, revoked the will leaving everything to her friend, and shortly afterwards died intestate. This settlement of the will in dispute brings about a remarkable change in the fortunes of a medical practitioner in the village of Rhynie, Aberdeenshire, who suddenly rises from obscurity and a humble practice to take up, by right of succession, the responsibilities and position of a Highland laird. Dr. Proctor, first cousin of deceased, and heir at law, is now at liberty to transport his wife and eight children from Aberdeenshire across his own broad acres in the neighbouring county of Banffshire, to enter the lordly halls of Aberlour House as master. Twenty-two years ago, the change of position was quite as singular for the last proprietor, who was the only child of an equally obscure medical practitioner in a Scotch village, and was left the estate by her uncle, Mr. Grant, a rich West Indian planter. The grounds of Aberlour House are guarded on east and west by picturesque lodges, beyond which stretch miles of beautifully kept carriage drives and avenues. The river Spey, with many a glorious salmon pool, bounds the property on the north; and behind the house, which stands on elevated ground, and ascending further still, you suddenly emerge upon a glittering mass of highly cultivated garden. It stands, with its miniature crystal palace, like an oasis in the surrounding moorland, from which it has been reclaimed. Instead, however, of making a state entry on this beautiful estate, we understand it is Dr. Proctor's intention simply to remove his door-plate from the village of Rhynie to the town of Aberdeen, there to continue the profession he enjoys. Besides the windfall of landed property to the heir at law, four poor relations come in, as next of kin, to £35,000 each in cash, after all expenses are paid.

#### LIME-JUICE AND SCURVY.

THE *Army and Navy Gazette* of December 15th contains some remarks on this subject, which one would have imagined could hardly have been written after the accumulation of evidence brought out by the Arctic inquiry. On the strength of a statement that there have been lately five cases of scurvy under treatment at the Seamen's Hospital at Greenwich, all from ships where outbreaks took place in spite of an ample supply of lime-juice, the writer says: "Disguise the matter as we may, there is no question of doubt that we have not in lime-juice the true preventative for scurvy." He farther states that it

is to steam, and not to lime-juice, that we are indebted for the diminution in scurvy that has taken place of late years. He then cites Surgeon-Major Oliver's opinion that it is the protein compounds that are the true antiscorbutics, and demands that experiments shall be made upon two sets of scorbutic patients, one to be treated with lime-juice, and the other with "one fresh raw egg three times daily, beaten up with half a pint of new milk with a little sugar; and let it be seen" (he adds) "which of the two divisions of patients will first improve and recover under this treatment". On the above statements, we may remark that it has hardly ever occurred that cases of scurvy alleged to have arisen in spite of distribution of lime-juice have stood the test of rigid inquiry. An attempt was made during the late Arctic investigation to prove that scurvy was beginning on board the ships before the sledge-crews started; but it was clearly shown that it occurred only in one or two men, who did not take their lime-juice and shirked their vegetables. As regards the statement that it is to steam, and not to lime-juice, that our recent immunity from scurvy at sea is due, we would simply ask him to look back to the history of the Royal Navy. Was it lime-juice or steam that in the short space of a few years banished a scourge that was destroying one man in seven so late as 1780? In 1805, scurvy had practically disappeared; but steam had not yet made its appearance. As regards Surgeon-Major Oliver's opinions about the efficacy of protein compounds, this is merely the theory of Sir R. Christison revived, although it was completely refuted by the late Dr. Parkes thirty years ago. Were it true, scurvy ought never to appear on a liberal meat-diet; but nevertheless it does. On the other hand, no amount of deprivation of albuminates will induce scurvy, if the diet have consisted of potatoes or green vegetables. Dr. Oliver's view so far differs from Sir R. Christison's, that he attaches particular value to fresh vegetable protein, whereas Sir R. Christison refers chiefly to animal albuminates. With regard to the experiment which the writer suggests, we would refer him to the very able pamphlet recently published by Dr. Ralfe of the Seamen's Hospital, where the question is treated in a philosophical spirit. He will there see that an experiment of the sort has actually been made, although not carried out quite so far. The result, however, showed that improvement did not take place until a true antiscorbutic was given, although a liberal diet with plenty of protein was allowed; the urine retaining its scorbutic characters until a nutriment containing the vegetable acids was administered. This outcry on the part of some persons against lime-juice is a little like the fanatical opposition to vaccination. The master-remedy has done its work, and has practically banished a foul and loathsome disease from among us; and now people begin to imagine that the remedy is useless, because it has done its work so well. It is like the rustic, who considered the moon much more valuable than the sun, because it shone at night, when it was dark; whereas the sun shines in the daylight, when he is not needed. Although we do not know everything about scurvy, yet all the evidence is overwhelmingly in favour of its being caused by the absence of fresh vegetable food; and, of all the constituents of that kind of food, the salts of the vegetable acids alone appear to be the efficacious agents. In the absence, then, of fresh vegetables, lime-juice is resorted to as the best and most easily managed substitute, and the test of experience has amply justified the trust reposed in it.

#### THE HEREDITARINESS OF MADNESS.

THE current of hereditary morbid tendencies presents various aspects in different families. There is the broad stream, which carries with it the taints of gout, consumption, criminality, as well as of insanity; each of these maladies being developed in different consanguine relations, in accordance with their moral and physical constitution, their habits and surrounding circumstances. There is the more limited transmission of the factors or influences, whatever these may be, which invariably culminate in certain forms of alienation or nervous diseases, but in no others; and, lastly, the heritage is limited to some particular species of mental disturbance—to suicidal tendency, for example. It

would be rash and unphilosophical to conclude either that suicide was frequently the result of hereditary vitiation; that it was a sign of moral perversion at all; or that it was other than the act of a distempered or agitated, but not necessarily of a diseased, mind. In glancing over the sad genealogical descents collected by Esquirol, Brierre de Boismont, and Moreau, there constantly recur instances where whole families devote themselves to self destruction, nearly at the same age, and apparently without any more appreciable incentive than *ennui*, disgust at life, or intolerance of incidents which would be regarded by healthier natures as insignificant and trifling. In like manner, such tragedies may be found closing an useful and prosperous career in several generations. In the endeavour to discover the cause of such conduct, inconsistent in many cases with the character and interests and habits of the victim, it is natural to adopt the nearest and readiest solution, especially when it seems sufficient to explain what would otherwise remain inexplicable; but that such a step must frequently lead astray cannot be doubted, when it is borne in mind that the laws of hereditary disease, even the fact and nature of such a taint, still remain in great doubt and obscurity; and that in the history of every individual there are thousands of physical affections, perverted sentiments, and wayward fancies and impulses, which are equally potent in bringing about self-murder, and even in overriding all other proclivities, whether these lead to hope and health or to trial and anxiety. Another element plays an important, though less conspicuous, part in leading to such catastrophes. We refer to the incitation, not to the blind impulse which precipitates various persons, strangers to each other, from the Monument or the Vendôme Column; but to that feeling which actuates members of the same profession, social group, or family, to resort to an act or a series of acts which have been perpetrated by those whom they love and admire, or upon whom they depend, and with whose opinions, dispositions, and course they have previously placed themselves, or been unconsciously placed, in harmony. These observations have been suggested by the death of the younger Prevost Paradol. This boy may have suffered from some constitutional type; but his age—seventeen—is as rarely influenced by transmitted taints as by grief, depression, or despair. In the absence of more reliable evidence, and in the knowledge that he must have been long separated from all direct paternal influences, and that the political or patriotic disappointment which hurried his father away from the contemplation of his country's misfortunes could scarcely reach the stripling, we are inclined to believe that some unknown influence—it might be the crisis of puberty—directed his thoughts to his father's last act; and that the similarity or identity of their inner nature suggested emancipation by following his example.

#### INSANITY OF MURAD V.

In the *Allgemeine Zeitschrift für Psychiatric* (xxxiv Band, 1 Heft), there is a long inquiry into the nature of the illness of the Sultan Murad V, of which an account is given in Dr. Maudsley's *Journal of Psychological Medicine*. It will be remembered that, during August of 1876, Dr. Leidesdorf of Vienna, was sent for, to be consulted as to the mental condition of the Sultan, and as everything must come to the public now-a-days, it is supposed that the different newspaper articles quoted contain the result of the observations of that learned physician. Apparently, insanity is hereditary in the house of Osman, as indeed it is in that of most European reigning families. Sultan Ibrahim was a maniac; Sultan Mahmud, a drunkard; Abd-ul Medjid, the father of Murad, died from the results of his excesses *in vino et venere*; and his uncle, Sultan Abd-ul Aziz, brought Turkey into its unfortunate condition by his indolence and his senseless extravagancies. Murad himself, a man of thirty-six years of age, of originally good constitution, was imprisoned by his uncle, and thought his life in great danger. In order to escape from the painful consciousness of his position, he was in the habit of indulging in spirituous liquors. Suddenly called by the deposition of Abd-ul Aziz to preside over the destinies of Turkey, at a most unhappy period of her history, he was deeply affected by

the violent death of his predecessor, and the frightful murder of his two ministers, Hussein Avni and Raschid Pacha, by the Circassian Hassen. These distressing events, acting on an exhausted constitution, caused continued sleeplessness, and finally plunged him into a deep melancholy. He told Dr. Leidesdorf that he had a feeling of constriction about the chest. "I live," he said, "two lives, one known to me, and clear to my comprehension, the other contained within it, obscure and incomprehensible. On my ascension to the throne, I saw everything full of flowers; now, the floor of my chamber, when I look at it, seems to be sown with bayonets." Dr. Leidesdorf thought that Murad might recover, if properly treated, in three months, a prognosis which was not well received by those who wished to dethrone him. He was said to be a man of a kindly heart, and more likely to be a good ruler than his successor, who only cared for himself. It is reported in the newspapers that he has now recovered; but, as he is still in a species of confinement, this cannot be exactly known.

#### A NEAPOLITAN HOSPITAL.

AN International Hospital has been established at Naples, at which are received patients of different classes at charges suitable to their conditions. There are three classes of accommodation, in the first of which separate rooms are provided, every expense included, at 7s. 6d. a day; those of the second class are received in common rooms at 4s. 6d. a day; and those in the general ward at 1s. 10d. a day. Nor are our seafaring and often suffering countrymen neglected, for every vessel paying a subscription of 7s. 6d. or 3s. 9d., has the right of sending any of its sick crew to the hospital at the rate of a fraction under 1s. 6d. a day each. The Consuls of the Netherlands, Switzerland, Russia, and England, in Naples, are on the Committee; also a French, German, and an English resident.

#### THE PUBLIC HEALTH.

DURING the week ended Saturday, December 29th, 4,608 births and 3,925 deaths were registered in London and twenty-two other large towns of the United Kingdom. The annual death-rate was 22 per 1,000 in Edinburgh, 23 in Glasgow, and 27 in Dublin. The annual rates of mortality per 1,000 last week, in the twenty English towns, ranged in order from the lowest, were as follow: Brighton, 18; Newcastle, 19; Bradford, 20; Leicester, 20; Hull, 21; Sheffield, 22; Salford, 22; Bristol, 23; Birmingham, 24; Portsmouth, 25; Leeds, 25; Nottingham, 25; Oldham, 26; Wolverhampton, 26; London, 26; Manchester, 29; Norwich, 29; Liverpool, 29; Sunderland, 33; and Plymouth, 33. Whooping-cough caused an excessive zymotic rate in Plymouth and Birmingham, and scarlet fever showed fatal prevalence in Sheffield. In London, 1,831 births and 1,757 deaths were registered. The annual death-rate from all causes was 25.9. The 1,757 deaths included 29 from small-pox, 109 from measles, 31 from scarlet fever, 12 from diphtheria, 82 from whooping-cough, 36 from different forms of fever, and 12 from diarrhoea; thus to the seven principal diseases of the zymotic class 311 deaths were referred, against 248 and 301 in the two preceding weeks. The 109 fatal cases of measles showed a further increase upon the numbers in recent weeks, and exceeded the corrected weekly average by 59. The 82 deaths from whooping-cough showed a considerable further increase upon the numbers in recent weeks, and included 38 in South London. The deaths referred to fever, which had been 26 and 41 in the two preceding weeks, were 36 last week, and were 4 below the corrected average; 7 were fatal cases of typhus, 23 of enteric or typhoid, and 6 of simple fever. The Metropolitan Asylum and London Fever Hospitals contained 157 fever (typhus and enteric) patients on Saturday last, against 173, 168, and 156 at the end of the three preceding weeks. The deaths from small-pox, which had been 31 in each of the two previous weeks, were 29 last week; of which 11 were certified as unvaccinated and 5 as vaccinated, while in 13 cases the medical certificates gave no information as to vaccination. The number of small-pox patients in the Metro-

politan Asylum Hospitals, which in the first week in October had declined to 137, was 309 on Saturday last; 83 new cases were admitted during the week, against 79, 85, and 84 in the three previous weeks. Thirteen deaths were referred to childbirth and puerperal fever. The deaths referred to diseases of the respiratory organs declined to 467 last week, and were 4 below the corrected weekly average; 310 resulted from bronchitis and 115 from pneumonia. Different forms of violence caused 50 deaths. In Greater London, 2,271 births and 2,014 deaths were registered, equal to annual rates of 27.1 and 24.1 per 1,000 of the population. At the Royal Observatory, Greenwich, the duration of registered sunshine in the week was 12.2 hours, the sun being above the horizon during 54.3 hours; the recorded duration of sunshine was, therefore, equal to 22 per cent. of its possible duration.

#### THE FRENCH SOCIETY OF HYGIENE.

A RECENTLY published pamphlet by Dr. de Pietra Santa states that the French Society of Hygiene consists of three classes of members: 1, titular, who pay twelve *francs* a year; 2, honorary, those who shall greatly assist in the work, or whose patronage would be useful; 3, foreign associates. Its objects are: 1, to give explanations in public of the great questions in hygiene; 2, to discuss at meetings matters relating to the science; 3, to award prizes for essays; 4, to publish papers; 5, to provide laboratories for analyses, etc.; 6, to form a library on sanitary subjects; 7, to make a collection of instruments, machinery, and models, bearing on hygiene. The chief part of the pamphlet is taken up with an address by Dr. de Pietra Santa, in which he reproduces Dr. Guy's definition of hygiene, and draws therefrom the deduction that it is better to prevent than to cure. He then referred to the work done by the Society; to the various sanitary associations in London, and especially to the National Health Society; and notices the laws of Holland relating to infectious diseases, which require the medical man to give notice to the sanitary inspector of every case he may be called on to attend, so that a board may be affixed to the house with the words "infectious disease" written upon it. He also especially discusses a lecture of Mr. Ernest Hart on the Sanitary Directions contained in the Laws of Moses. The address is largely made up of a critical *résumé* of sanitary work carried on in England and elsewhere.

#### THE ACTION OF CURARA.

A CORRESPONDENT forwards us the following report of the action of curara, employed in two cases in which it was desired by their owner that two animals should be destroyed by an easy death. Sir William Jenner observed to the Home Secretary, when the Act for controlling experiments on living animals was under discussion, that, if a man chose to drown a dozen kittens or dogs just because he wanted to get rid of them, no one could have anything to say to him; but, if he made the phenomena of death under such circumstances the subject of scientific investigation, with the view of deriving any beneficial knowledge which might be obtainable from the investigation, or of the action of poisons ultimately producing death, he would be liable to prosecution. The author of the following notes, in forwarding them to us, unconsciously illustrates this observation by writing at the same time: "I think it will be well not to mention my name in publication, lest undue advantage be taken thereof."

1. Six minims of a solution of curara in water (one grain to twelve minims), equal to half a grain, obtained of Messrs. Corby and Co., Holborn, were injected beneath the skin of a healthy kitten, three months of age. After ten minutes had elapsed, a weakness of the hind legs was remarked; in half a minute or so more, a decided stagger in the gait. The animal then lay down on its chest, shortly afterwards turned on its left side, and there were slight convulsive movements of the upper and lower extremities. Respirations were 40 in the minute. These soon ceased, but the heart's pulsations were easily felt, 120 in the minute. The pulsations became more feeble, and, in seventeen minutes and a half from the time of injection, had ceased altogether. The muscles were flaccid, the pupils dilated. The tongue was in apposition to the roof of the mouth. A very small quantity of urine was

voided. *Post mortem appearances.*—Rigor mortis was strongly developed in twelve hours. The thorax was flattened. The posterior part of the right lung was congested. The other parts of the lungs were scarlet. The right side of the heart (both cavities) was full of dark fluid blood. The cardiac veins were filled. The left side was in systole; both cavities were empty. The abdominal veins were all filled. The intestines were natural. The kidneys and spleen appeared normal.

2. Twelve minims of the same solution, equal to one grain, were injected beneath the skin of a healthy cat, between two and three years of age, at 5.10½ P.M. At 5.15, a weakness of both extremities was noted. This increased; the animal uttered a feeble cry or two. At 5.16½, she lay with her head between her paws, like a hare in form. Respirations 22. There were slight convulsive movements of the body; the tail moved from side to side. At 5.18, respiration stopped. The heart's pulsations fell, 168 in the minute. At 5.20, the pulsations were 126, more feeble; they became intermittent. The animal passed urine. At 5.22, the pulsations were 84. At 5.23, the heart's action ceased. The pupils were widely dilated. The tongue was apposed to the roof of the mouth, with the tip between the teeth. The *post mortem appearances* were exactly the same as in the former case, with the exception of the lungs being very much more congested, and dark on both sides.

#### MEDICAL ORGANISATION IN PARIS.

IN a note on the Organisation of Public Assistance in Paris (published as a separate pamphlet in French), written partly to report to the French Society of Hygiene the results of a visit to the Leamington congress, M. Clement Couly speaks in high terms not only of the work carried out by the Sanitary Institute, but also of that performed by the Royal Humane Society; and refers warmly to the amount of good effected in England by individual workers, as compared with centralisation in France. He then notices similar action taken in Amsterdam and Madrid, and gives an account of the provisions for relief of the wounded and assistance to the drowning in Paris, which are afforded under the control of the municipality and with the aid of the Préfecture of Police. M. Couly states that between May 1st, 1875, and May 1st, 1876, thirty-seven persons were taken out of the Seine to one of the six tents (*paravents*) belonging to the municipality, and thirty-two were restored to life. He also notices the public night medical service, consisting of 532 doctors of medicine, 32 officers of health, and 99 midwives, the number of whom is said to increase almost daily.

#### ACTION OF ANTISEPTICS.

IN a brochure entitled *La Septicémie Expérimentale* (Paris, Adrien Delahaye & Cie., 1877), Dr. J. V. Laborde publishes the results of a series of experiments on the preventative and curative action of reputed antiseptics, that especially deserve attention at the present time. In order to produce a septicæmia that should be independent of secondary changes produced by the injection of septogenic material into the subcutaneous connective tissue, he selected the method of arterial communication of Alphonse Guérin. A dog having been made septicæmic by the direct introduction of septic blood into a vein, the femoral artery is laid bare and its central end is placed in direct communication with the separated distal end of the femoral artery of a healthy dog. The second dog which receives the septicæmic blood in this manner becomes itself septicæmic. By successive "generations" produced by this operative procedure, a blood is obtained containing the septicæmic poison in a high degree of intensity. In regard to the presence of organisms in this moribgenic fluid, Dr. Laborde remarks that "the blood of a dog infected by arterial communication has never, when attentively examined at different periods of the disease, exhibited the presence in appreciable quantity of microcytes—bacteria, vibrios, granular matter, etc.—not even in cases in which the blood primarily inoculated contained microzoa in more or less large numbers: so that we find ourselves in presence of a disease which can be transmitted indefinitely without the intervention of inferior organisms". In contradiction to the statements of Binz, the author found that quinine, even when injected in the highest doses compatible with life, neither acted as a pre-

ventative to the development of the disease, nor arrested it when it was produced. Similar negative results were found with chromic acid, carbolic acid, bichromate of potash, and permanganate of potash.

## SCOTLAND.

THERE was no death from fever, diphtheria, small-pox, or scarlatina in Edinburgh last week. The only deaths reported from measles occurred on the south side of the town.

### SANITARY IMPROVEMENTS AT INNERLEITHEN.

ON Monday last, the inhabitants of Innerleithen held holiday in honour of the completion of a scheme of sanitary improvements which has just been accomplished. The undertaking in question, which embraces the supply of the town with water, and the introduction of an efficient system of drainage, has been carried out since May last. For water-supply, the inhabitants have depended hitherto solely on pump-wells, the water in which, however, had become so contaminated by organic matter as to be pronounced unfit for domestic use. The present supply is taken from the Bold Burn, a clear stream at some distance from the town. Piping has been laid down for about seven miles. As no storage for compensation purposes is required, the whole flow of water from the gathering-ground, which is calculated at half a million gallons a day, can be made available, if necessary, for the requirements of the town. This, however, is greatly more than is at present required. For drainage purposes, the town occupies an exceptionally favourable position, all the inclination being in one direction. The outfall will be into the tail-race of a mill-lade, into which, in summer, most of the water of the Leven finds its way. Due advantage is taken of the gravelly nature of the soil for filtration purposes; so that the discharge into the tail-race will be in a comparatively pure state. At every junction of the drainage-pipes, and at the end of each branch main, a man-hole is constructed, having one of Baldwin Latham's ventilators, with charcoal basket for filtering the gases before they escape into the open air. The flushing of the sewers will be carried out by means of branch-pipes from the water main led into the manholes, which are filled with sluice valves. The arrangement secures not only that the sewers shall be copiously flushed, but that at the same time any sediment gathering in the water main will be discharged. A large company assembled to see the opening of the new works.

### INFECTION IN THE LAUNDRY.

AT Greenock, on Saturday, a woman was fined ten shillings, with the alternative of five days' imprisonment, for having sent to be washed, in a public washing-house, blankets infected with disease. Three persons were admonished for not having reported to the Sanitary Authority the presence of scarlet fever and measles in their houses. These were the first cases of the kind which have been brought under the new Greenock Police Act. How often do not well-to-do persons, in all parts of Great Britain, pursue with impunity the same reckless and dangerous course.

### COMFORT FOR ADULTERATORS.

SEVERAL milk adulteration cases, which had been postponed pending the decision of the Court of Session in a case of which we gave the particulars a fortnight ago, were to have been brought before the Sheriff of Glasgow last week by the Sanitary Inspector. Owing to the recent decision of the Court of Session, the Sanitary Inspector withdrew the charges. Thus the Adulteration Act has become in Scotland a dead letter, as far as food is concerned which is not contaminated by any substance actually injurious to health. Milk and similar substances may be diluted with any quantity of water, and cream with any quantity of skimmed milk, to any degree of tenuity, and yet the Sanitary Inspector has, say the judges, no power to prosecute. A private individual may get damages, in that he did not get the article for which he paid; and we know how few private individuals care to go to the trouble and expense of prosecuting anybody; but the public prosecutor has no such

power. We only want a lenient view, as to what may be considered injurious to health, to make the law absolutely, or nearly absolutely, useless. Can it be proved, for instance, that alum in bread, unless in very large quantity, is injurious to health, or that adding salt to beer is likely to be to the buyer's prejudice? If not, then farewell to pure bread and unadulterated beer.

## IRELAND.

THE Duke of Connaught has forwarded a cheque for £100 to the Mayor of Cork, to be distributed amongst the local charities of that town.

### BELFAST HOSPITAL SUNDAY.

ON the 30th ult., being the last Sunday in the year, collections took place in twenty-seven churches in Belfast for this charitable purpose. In January, collections will also be made in other churches for the same object. The funds obtained at the various places of worship will be handed over to the Belfast Royal Hospital, the only general hospital in the town.

### CHARGE AGAINST A MEDICAL PRACTITIONER.

A PROSECUTION is at present pending against Dr. O'Hare, residing at Castle Street, Belfast, on the charge of forging a writ, in order to intimidate a patient to pay an account for medical attendance. Bail has been refused, the charge being a very serious one.

### HOSPITAL FOR SICK CHILDREN, BELFAST.

THIS hospital having been found too limited to afford sufficient accommodation for the number of applicants for admission, a new building is in course of erection, and, to supplement the funds, a bazaar was held on the 20th ult. in the Ulster Hall, Belfast. We are glad to state that the bazaar has realised the handsome sum of £1,500, not including donations, which amounted to £200 more.

### DISPENSARY APPOINTMENTS.

AT a meeting of the Dispensary Committee of the Clonbrock District of the Mountbellew Union, held on the 27th ult., Dr. Richard O'Reilly, resident medical officer of the Limerick Union, was unanimously elected medical officer. The emoluments of the post are £135 a year, with registration and vaccination fees. Dr. Ambrose was elected, last week, medical officer of the Ahascragh Dispensary District of the Ballinasloe Union at a salary of £50 *per annum*.

### CLINICAL INSTRUCTION AT THE BELFAST WORKHOUSE HOSPITAL.

AT a meeting of the Belfast Board of Guardians held last week, a discussion took place in reference to this matter. It seems that the authorities of the Queen's College were anxious that the medical students should have the advantage of the clinical instruction which the hospital and infirmary of the workhouse afforded; and, at an interview, some time since, between them and the guardians, it was arranged that the latter should give every facility as far as they could in accordance with the proper discipline of the house. It was also agreed that Drs. Smyth and McConnell should have the same status as clinical instructors as the medical officers of the Belfast Royal Hospital. The question of remuneration, however, upset the whole arrangements; for, as the fees of the students were divided equally among the medical officers of the Royal Hospital, and as they did not wish to curtail their emoluments by transferring a portion to Dr. Smyth and his colleague, it was suggested that an increase of fees should take place, so that the amount per share might remain as formerly; but the College authorities made objection to this procedure, and so the matter remained as before. The subject was now brought forward for discussion, and it was agreed by the guardians that copies of the rules adopted by the Board as to the admission of medical students to the Union Hospital for clinical instruction should be forwarded to the Chief Secretary for Ireland, requesting him to cause an inquiry to be made why the opportunity afforded the students had not been embraced.

## THE GAZETTE HEBDOMADAIRE ON THE BRITISH MEDICAL JOURNAL.

THE *Gazette Hebdomadaire de Médecine et de Chirurgie*, in a recent number, gives a brief sketch of the history of the British Medical Association, in which it does us the honour, in describing the BRITISH MEDICAL JOURNAL with some detail, to speak of it as the most important scientific journal in the whole world ("le journal scientifique le plus important du monde entier"). Coming from a medical periodical which has itself for many years stood at the head of French medical journalism, and is distinguished for the seriousness of its scientific work and the deliberate importance of its criticism, we cannot but highly appreciate so extremely flattering a judgment from so important and well skilled a critic.

### REFORM OF THE CORONERS' COURT.

MR. W. H. MICHAEL sends us the following memorandum on the office of coroner, as part of a complete scheme of local government.

- a. Creation of a Ministry of Health and Justice (central authority).
- b. The Minister of Health and Justice to have a seat in the Cabinet.
- c. Division of the country into districts. Each district to have one local authority for all purposes of local government, with all necessary powers of rating, etc.
- d. Constitution of county authorities, as Boards of Finance, for joint works, and for carrying on county asylums, etc.; also as a Board of Appeal on questions arising between district authorities or their constituents, with an ultimate appeal to the central authority. These boards to be representative in character; one-half the members to be the chairmen of the various local authorities within the county; the remaining half to be chosen by the magistrates in Quarter Sessions assembled, and to consist of persons representing large ratepaying interests. Election to be annual.
- e. Organisation of a Public Medicine Department by the State (State Medicine) on similar lines to those regulating the Army and Navy Medical Services, with similar grades of officers—Inspectors-General to assistant medical officers of health; appointments to districts as to regiments or ships, etc.
1. Coroners to be appointed and paid by County Board.
2. To be persons having had the advantage of legal training.
3. Juries to consist of not less than twelve persons; the verdict of the majority to be taken.
4. Inquests to be held *super visum corporis*, for the purpose of inquiry into the cause of death; also as to shipwrecks and fires in all cases; also treasure trove, etc.
5. Coroners to have no power of issuing warrants of committal to prison. No prisoner to be tried on the coroner's inquisition. Facts to be inquired into as affecting persons charged with homicide before magistrates, and depositions returned into court. Juries to determine the cause of death only, without determining between the crimes of murder, manslaughter, etc.
6. Coroner's inquisition to be certified under seal to the Public Prosecutor. One or more Public Prosecutors to be appointed by the central authority for each county.
7. *Post mortem* examinations, when directed by the coroner, to be after hearing the evidence in all cases of medical attendant: such evidence to be forwarded to medical officer of health, whose duty it would be to conduct the *post mortem* examination; to attend the inquest; to make a report, if necessary, requiring further information from the medical attendant, and stating whether it was necessary to have any, and what, chemical analysis performed. Coroner to direct analysis. Such analysis to be performed by the public analyst attached to each local district. (Appointment of local public analysts to be made by district local authorities.)

DR. R. T. WRIGHT, Coroner of Shropshire (Bradford North District) writes:

Permit me to mention the opinions which I have formed as the result of nearly twelve years' experience of medico-legal cases in England, in Scotland, and in India, where the civil surgeon of a district (equivalent to medical officer of an English county) is obliged *ex officio* to perform many of the functions discharged by a coroner at home.

I fear we must separate what is desirable from what is practicable,

as the question of expense forbids us to hope for the establishment of any court so complete and elaborate as was recommended at the Coroners' Conference, and by some of your esteemed correspondents.

*Legal or Medical Coroners.*—Will any one conversant with medico-legal cases deny that in eighty per cent. of sudden deaths, with or without inquests, medical knowledge is of more importance to the coroner than legal? If he do, I beg respectfully to refer him to superintendents of police, both in England and India, who will, I believe, confirm my opinion. Why have a coroner useful only in one-fifth of the cases?

*Appointment.*—Whether legal or medical, the coroner should be appointed and paid by the Crown, the responsible advisers of which could be trusted to select only a man of special attainments, who should hold office during good behaviour, but with a pension after certain service, and who should have charge of a district large enough to give him ample experience and to fully occupy his time, to the exclusion of other than public duties. He must be a man of common sense, so that no scandals may occur like that which shocked society on the death of Sir Charles Lyell. No inquest or *post mortem* examination should be made unnecessarily, and a monthly return of all inquests and sudden deaths should be made to the Medical Officer of the Privy Council, who should have censorial and disciplinary powers over all coroners. Civil Surgeons make such a return to the Surgeon-General of the Indian Medical Department, and the plan works well. In Scotland, the Procurator-Fiscal makes an inquiry into sudden deaths, which is kept private or made public at his discretion, and it is highly desirable to give the English coroner the same power, as no one will say it is abused in Scotland.

*Court.*—The procedure is so simple that any surgeon of intelligence who has seen a few inquests can hold the court, and conform to the law, if he only studies Sir John Jervis on *Coroners* and Sir James Fitz-James Stephen on the *Law of Evidence*. The coroner is a judge of a court of record, and it is absurd to say a surgeon or physician who has read these books cannot preside in a coroner's court because he does not understand evidence, for he has only to report to superior courts whether any one is to blame, or not, in cases of sudden death. All sudden deaths should be reported to the coroner and included in his return to Government whether he considers an inquest necessary or not.

*Referees.*—A coroner is allowed to consult a referee in cases requiring technical knowledge, as deaths from accidents in mines, in ships, or on railways; why should he not be allowed to consult experts in law,\* chemistry, medicine, surgery, pathology, etc., on exactly the same footing? In India, each Local Government has an officer called the "Chemical Examiner to Government"; and an idea may be formed of the amount of work this gentleman performs when it is mentioned that he has about two cases every day, on a yearly average, to analyse and report upon. His written report is considered as evidence in a court of law, and he is summoned to give evidence in person only in a few important cases.

On the staff of the Medical Officer of the Privy Council there should be a number of well-trained analysts, one to each district, the area of which should be determined by Government, and all the coroners of the district, circle, or circumscription (or whatever you call it), should be compelled to consult him whenever the local practitioner so advised. It is absurd and ill-natured to ignore the local practitioner, as his evidence is generally of more value than that of all the other witnesses, and the coroner should be compelled to summon him. Magistrates object on the ground of expense, but magistrates should not be allowed any voice in the matter, as they are not qualified by their education to form an opinion on medico-legal questions.

Since the Penge case, *post mortem* appearances are in bad odour, and it will be probably generally allowed that ordinary practitioners unconnected with hospitals have not sufficient experience in such phenomena. As they practise midwifery, it is not desirable that they should make *post mortem* examinations, but this duty might very properly be done by the district medical officer of health (who is debarred from practice), and his pay should be raised on account of this addition to his work; but he should make the examination in the presence of the local practitioner who knew the deceased.

*The Jury.*—The jury was originally appointed to identify the body of the deceased, and to assist the coroner by their local knowledge to find out if any one were to blame or not for the death. I see no good reason for limiting the number to twelve jurors. By the present law, more than twelve are summoned, in order that twelve may agree

\* Why should not a coroner be at liberty to take the opinion of an expert in law? At assizes, the judges often confer with each other on knotty points; at the same time, they are assisted by the arguments of counsel and references to statutes and law-books. Would judges like to hold assizes without barristers to plead before them? yet barrister is only another name for the expert in law, whose services I claim for the coroner.

in their verdict: if they do not, they are adjourned, without food, drink, or fire, till next day; and if, still, twelve out of the fifteen or twenty cannot agree, the inquest may be adjourned till the next assizes, when they can have the assistance of a judge to aid them in coming to a decision. This is good sense.

*Rank.*—Your correspondents rightly urge that a coroner should be a magistrate. At present, he is only a subordinate judge of court of record, and the office is sought by medical men and lawyers to aid them in becoming known; but now-a-days, when so much technical knowledge is required, coroners should be medical men of special qualifications, and when appointed should be made magistrates *ex officio*, sitting on the Bench with other magistrates whenever they choose, having exactly the same rank. They should be appointed by the Crown, as no other authority can be trusted to make a proper selection. The present mode of election by the freeholders is absurd and most expensive. No coroner should be put to a farthing's expense for his appointment, which should be simply notified in the *Gazette*.

At present, a coroner must be a *freeholder*. This was a necessity in bygone ages, but is now an absurdity.

A very short Act of Parliament could brush away all anachronisms, and give a coroner as much power and rank as may be required to make him an useful and respected officer of State.

MR. H. M. CHAMPNEYS of Penge writes:

I think it most important and necessary that to every coroner's district should be appointed a public medical officer, who should be present at every *post mortem* examination, and that he should also when requisite make an analysis. It would, therefore, be necessary to appoint a highly qualified gentleman for this office, whose remuneration should be such as would preclude any necessity for private practice, though he would be a very valuable auxiliary in special consultations. In every case, the medical man in attendance should be present. The present system does not work satisfactorily. I will mention two cases which have occurred to myself.

I was called to see a child said to have been overlaid; it had been dead some two hours. I refused to give a certificate. The police informed the coroner, who sent word that I was to make a *post mortem* examination if I thought one necessary. I, in company with two friends, made one, and found a "fractured skull and extravasation on the brain". An inquest was held; I was not called; and the verdict, I afterwards ascertained, was "Death from natural causes".

Some months since, I was called at 5 A.M. to see a domestic servant. She had been dead three hours. She had not been well the previous evening, but had done her work, went out to see her mother, and to the chemist's, from whom she obtained some medicine, a dose of which she took on going to bed at 10 P.M. I refused a certificate. The police, as before, acquainted the coroner, who sent me a similar verbal message as in the former case. I was to make a *post mortem* examination if I thought it necessary. I declined to do so without an order. The mistress obtained the services of the district medical officer's assistant, who made a *post mortem* examination, at which, though invited, I declined to be present. In his opinion, there was sufficient "inflammation of 'one lung' to account for death"; and he gave a certificate. No analysis was made. I think, in this case, there ought to have been an inquest.

Dr. Charles Graham, himself a coroner, says, in the *JOURNAL* of December 15th: "If Mr. Carttar's plan of ordering *post mortem* examinations, and then deciding himself as to the propriety" (it should be, I think, necessity) "of holding an inquest, were permitted, it would save much trouble and expense to the county, but I think it requires a medical coroner to decide this important question." I think differently. The coroner would simply, in this case, be acting on his view of the report or statement of the gentleman making the necropsy; and there must frequently be present many reasons why the whole circumstances of the case should be laid before the jury, and it is probable that a scandal would sometimes arise from a *post mortem* examination being made and no inquiry following. The expense ought not to be a question in these cases.

MR. J. HIGHAM HILL writes:

I have, during the last ten years, as Resident Medical Officer at the Royal Free Hospital and at St. Pancras Workhouse, personally attended and given medical evidence at more than six hundred inquests, and have been present at considerably more than double that number. My opinion is that the present machinery would, with some slight improvements, when duly and properly exercised, be ample to meet all reasonable and just requirements. It is highly desirable that the coroner should be a member of the medical profession and a gentleman of good professional and social position. In by far the majority of

cases, an inquest is altogether a medical inquiry as to the cause of death; and in any case tried before a coroner's court, the legal points are so limited and plain, that I believe that any well-informed and properly trained medical man who has obtained the position of coroner can direct the jury as well and ably as the occasion requires, besides being able to assist and direct them from a medical point of view. I have known many instances where the latter qualification has clearly been of great value.

With regard to the mode of election of coroners, I think that the candidate for the office should be nominated by a county or borough magistrate, and that the electors should be the freeholders on the franchise lists. The election of by far the majority of coroners has, for nearly a thousand years, been entrusted to the people, whose deaths, lives, and interests, it must be his chief duty to watch over and guard; and I do not think it ought to be placed in the hands of some State official to dispose of as he may think fit.

In reference to the question of having special officers appointed to make *post mortem* examinations, such a procedure would, in my opinion, be a most unwarrantable attack upon the honour, intelligence, and independence of the profession at large, and ought to be strenuously resisted. It would materially increase the expenses in most cases, as the expert would be required to give evidence upon the *post mortem* examination and the medical attendant upon the *ante mortem* symptoms, etc. I have witnessed a very large number of practitioners perform *post mortem* examinations, and from what I have seen and heard, I am of opinion that, as a rule, to which there are few exceptions, the medical men of the present day are quite equal in manual dexterity and pathological knowledge to the requirements of the subject, having due regard to law, public safety, and reason. I think, however, that the coroner should have the power in any case of death under direct or implied suspicion of foul play to call in, if he deem it necessary, and pay some recognised and appointed expert in pathological knowledge, such as the pathologist to a hospital, to aid the medical man in charge of the case, and they should report to the coroner as to the advisability or otherwise of submitting certain portions of the body to a duly appointed analytical chemist for analysis, which report the coroner should be empowered to act upon at once.

I am of opinion that in many cases a more full and strictly conducted preliminary investigation of the circumstances attending the death ought to be made by a competent and trustworthy officer; and after that, should an inquest be deemed necessary, one should be held in due form, a *post mortem* examination being made and the results properly recorded, whenever requisite to enable the actual cause of death to be clearly and definitely ascertained, if possible. In many instances, at present, the jury assemble at very considerable inconvenience to themselves to ascertain the cause of death of a person, and to return a true verdict thereon, and, for want of a *post mortem* examination, a very imperfect, and probably untruthful, verdict is returned; the sole result being that an expensive legal farce has been performed, and some such verdict as "Found dead in the waters of the Regent's Canal" returned—the mere statement of a fact which was well known before the Court assembled. I need scarcely say that the actual cause of death in such a case may have been a very different one from drowning; but, for want of a *post mortem* examination the case remains shrouded in mystery, and an easy mode of disposing of a dead body is published.

## CHRISTMAS IN THE LONDON HOSPITALS.

THE recent festive season has been regularly observed by the patients in the Metropolitan Hospitals. The men, women, and children have all been regaled in a manner suited to their various tastes; and, where possible, the strictness of hospital regulations has been relaxed for the time being. We are enabled to furnish the following details respecting the doings at some of the hospitals.

### CHARING CROSS HOSPITAL.

AT Charing Cross Hospital, on Christmas Day, the patients were allowed to regale themselves with a liberal dinner of roast beef and plum-pudding, where the medical orders did not forbid the same; and we may rest assured that, if error there were, it was on the side of too much indulgence towards the patients. The wards were not decorated to any extent, in deference to the wishes of the sisters in charge, who feared that the work necessary for such decorations would lead to disfigurement of the walls of the wards, which, since the reopening of the hospital, have been admired by all visitors. A very beautiful Christmas-tree was, however, to be found in the children's wards, and was

very prettily got up with all kinds of articles likely to please the inmates of the wards, which are amongst the most tasteful in the hospital. Numerous visitors attended and distributed the riches of the Christmas-tree to the children. The men were allowed to smoke in the evening; and it is satisfactory to think that no one has been the worse for the relaxation from hospital discipline. On Thursday next, the operating theatre will be turned to other than its usual purposes. We understand that a magic-lantern and like pieces of amusement will entertain the patients.

#### GUY'S HOSPITAL.

Christmas at Guy's Hospital was of the usual festive character. The inmates were regaled with an ample allowance of roast beef and plum pudding, to which the majority did ample justice; and an important adjunct to the meal, in the shape of dessert, with pipes and tobacco for the male wards, and toys and bonbons for the children, was liberally contributed by the students. All the wards were gaily decorated with holly and flowers, natural and artificial, according to the bent of their respective sisters, who were ably seconded in their efforts by the dressers and resident staff, who had spared no pains to make their work effective. A large body of ladies and gentlemen visited the wards at dinnertime to express sympathy with the patients, and to wish them, with the compliments of the season, a speedy return to health, and at the same time, to admire the flowers and devices, which all agreed were unusually attractive. On account of their novelty, the arrangements in the clinical and Luke wards are worthy of special notice. In the former, apart from the ordinary decorations, an energetic clinical assistant surpassed all previous ingenuity by extemporising a primeval forest over the central fireplace, while the latter was emblazoned with some excellent and appropriate cartoons combining the *genius loci* with the amenities of Christmas-time. One of these, the work of a former house-surgeon, is likely to attract more general and lasting attention, not only on account of its intrinsic excellence as a work of art, but as a practical commentary on the topics of the day, as exemplified by the lady-doctor mania. The picture is entitled "Guy's in 1877", and represents the operating-theatre crowded with golden-haired graduates, viewing, with evident satisfaction, the operation of the day, which the notice-board informs us is excision of the heart, male. After a brilliant performance, the organ is being held up by the lady operator in conscious triumph that she has surpassed her male predecessors, while the offices of sisters and nurses have descended to bearded members of the latter sex, with whom, by the way, another notice informs us, "the students are requested not to flirt". In the background, battling with the billows, are some excellent representations of the present esteemed surgical staff, hopelessly cast adrift from their moorings on the great ocean of the future. The picture, we believe, is a present from the artist to his old teacher, Mr. Cooper Forster, and is well worthy of a visit from all old Guy's men. The festivities passed off pleasantly; and next day, the patients professed themselves to be all the better for the temporary indulgence.

#### KING'S COLLEGE HOSPITAL.

The festivities were on a small scale. On both Christmas Day and New Year's Day the male patients were supplied with tobacco and whisky, and the female with sherry. The "sisters" visited the wards in the afternoon and sang carols. In the evening the residents went into them and sang songs, joining in with the patients. It is intended to have a Christmas-tree for the children about the 14th of the month.

#### ST. MARY'S HOSPITAL.

On December 27th, the annual Christmas entertainment was given to the patients. The arrangements had been so carefully made by Miss Williams and Mr. Juler, that it was impossible that they could result in aught but success. House-surgeons, sisters, and nurses had been for many days preparing a gigantic Christmas-tree, which was illuminated in the board room at about 6 P.M. The boughs were so richly laden with the fruit of the work of thoughtful friends that, bending under their joyous burden, they nearly upset the equilibrium of the 101 blazing tapers; and it seemed as if the tree itself could only consummate its happiness in a gorgeous conflagration. One of the hand fire-engines, however, with which the hospital has been lately provided, was close at hand, but its services, which might probably have cast a damp over the whole assembly, not being required, it eventually retired to its corner in sulky silence. The great feature of the day was the able impersonation of Old Father Christmas by Mr. Thomas Norris, of The Lodge. He was so active in his distribution of toys, and other and equally useful presents; so ready to the call of the many anxious little voices, that it is no wonder that he was unrecognised by his oldest friends. After the tree had been dismantled (in considerably less time

than it took to dress it) a concert and readings were given by various friends. Perhaps this part of the entertainment might have been more appreciated (if that were possible) if the music had been a little lighter and more cheerful; so also with some of the readings. Hospital patients cannot keep their attention long fixed, nor care to have it drawn to pictures of sadness. When the patients had left for the wards a dance, in which the resident officers, sisters, nurses, and visitors joined, brought a most successful evening to a close.

#### WESTMINSTER HOSPITAL.

The wards were decorated much as usual: but being just out of the builder's hands, they looked prettier and brighter than usual. The patients were regaled with the ordinary Christmas fare.

## HOSPITAL AND DISPENSARY MANAGEMENT.

#### THE SALFORD AND PENDLETON ROYAL HOSPITAL AND DISPENSARY.

We have received the annual report of the above-named Hospital. It describes its career as "a glorious success", and adds, "for the fiftieth time, the Institution appeals for more annual subscriptions. Let this year be in truth a jubilee!" But those who take a large view of medical charity, and who can look beyond the interests of any particular hospital or dispensary, will not find much cause for jubilation in this report. To tell us how the number of patients has gradually increased from sixty a week to more than two hundred a week, is a proof of success which will satisfy only those who know nothing about the subject. The report goes on to say: "During the past year, the circumstances of every individual recommended for admission to the benefits of the charity have been carefully inquired into by a trained visitor; and the Board can with confidence state that the whole of the seven thousand and seventy-three out and home-patients who have received medical or surgical treatment were fit and proper objects of charity and unable to help themselves." This is all very well. But, as our readers are aware, there is in Manchester and Salford a Provident Dispensaries' Association, which is desirous of co-operating with all the medical charities, and is willing to investigate their cases for them, with the view of bringing the whole system of medical relief into harmony with the improved condition of the working classes at the present day. From this Association the Salford and Pendleton Hospital stands aloof. We cannot but think that its investigations would be more thoroughly and more economically carried out if it were to co-operate with the Association; and it would then help, and not hinder, the important experiment in medical relief which is now being made in Manchester.

#### SHILLING DISPENSARIES.

EVERY good thing is liable to spurious imitations. The provident dispensaries which are now being multiplied all over the country, to the advantage both of the poor and the medical profession, are being followed by a plentiful crop of "shilling dispensaries". The latest example of this class of dispensaries to which our attention has been drawn, is at Dorchester. From a recent number of the *Dorset County Chronicle*, we learn that "Mr. E. J. Day, surgeon, has opened an institution of this useful and commendable character at his residence on Fordington Green". The third rule states that, "by paying 1s. when patients attend the first time in each week, advice will be given, and one, two, or three bottles of medicine, as the case may require, provided the three visits are within the seven consecutive days". The fourth rule informs us that "all pills will be coated, in order to render them perfectly tasteless". The eighth rule states that "maternity cases are attended in Dorchester and Fordington for 7s. 6d.". The tenth rule says: "The fee for removal of a tooth is 1s.; but, on payment of 2s. 6d., it will be extracted without pain by means of laughing gas (nitrous oxide)." The fewer that we have of these "useful and commendable" institutions the better. They are sure to degrade the medical profession, and to pauperise the patients. We wonder that Mr. E. J. Day is not afraid that all the old women in Dorchester who attend midwifery cases will rise up against him for infringing their prerogative.

BEQUESTS.—Mrs. Julia Ann Dobie, late of Houghton Place, Ampt-hill Square, who died on September 14th last, has left £300 each to the Hospital for the Paralysed and Epileptic, the Victoria Hospital for Children, the Royal Free Hospital, University College Hospital, and the Seaside Convalescent Hospital.

## ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL:  
NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 9th day of January next, at Two o'clock in the afternoon.

FRANCIS FOWKE,

*General Secretary.*

36, Great Queen Street, London, W.C., December 22nd, 1877.

## BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

The next meeting will be held in the Examination Hall of the Queen's College, on Thursday, January 10th, 1878. The Chair will be taken by the President, SAMPSON GAMGEE, Esq., at Three o'clock P.M.

Mr. Gamgee will exhibit a new form of Sayre's Apparatus for the Treatment of Spinal Disease.

The following papers are promised.

1. Dr. A. H. Carter : On the Determination of Sugar in Urine.
2. Dr. Foster : On Sudden Death in Diabetes Mellitus.

JAMES SAWYER, M.D.,

EDWARD MALINS, M.D., } *Hon. Secretaries.*

Birmingham, January 2nd, 1878.

## BATH AND BRISTOL BRANCH.

THE third ordinary meeting of the Branch will be held at the York House, Bath, on Wednesday evening, January 30th, at a quarter past Seven o'clock : H. MARSHALL, M.D., President.

The evening will be devoted to the discussion of Hospitalism, which will be opened by R. W. Tibbits, M.B.

R. S. FOWLER, }

E. C. BOARD, } *Honorary Secretaries.*

Bath, December 31st, 1877.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT  
MEETING.

THE second ordinary meeting was held at the library of the County Hospital, Canterbury, on Thursday, November 22nd, at three o'clock. There were present, Mr. RIGDEN in the Chair, and nineteen members.

*Resignation of Honorary Secretary.*—Mr. THURSTON, the Honorary Secretary, tendered his resignation, and stated that pressure of work, caused by increasing practice and the lamented death of his partner, compelled him reluctantly to take this step.

Mr. REID proposed the following resolution, which was seconded and carried unanimously: "This meeting, on behalf of the East Kent District of the South-Eastern Branch of the British Medical Association, while expressing deep regret at the circumstances which have compelled Mr. Thurston, though greater demand on his valuable time, to resign the secretaryship of the district, desire to tender him the cordial thanks of the members for the kind, zealous, and business-like manner in which he has uniformly carried out the duties of the office, and also for the material improvement he has effected in the character and strength of the meetings."

*Election of Secretary.*—Mr. W. Knight Treves of Margate was elected to succeed Mr. Thurston.

*Papers.*—Mr. T. WHITEHEAD REID read a case of Poisoning by Vew-Leaves (reported in the JOURNAL for September 29th, at p. 442).

Mr. TYSON read a case of Poisoning by Phosphorus.

Mr. RIGDEN read a report of two hundred Forceps Cases which had occurred in his practice during the last eighteen years.

Interesting discussions followed each of these papers, in which Dr. Lochée, Dr. Parsons, Dr. Lewis, Dr. Bowles, Mr. Garraway, Mr. Hayward, Mr. Thurston, and other members, took part.

*The Next Meeting* will take place at Dover; Dr. Robinson in the Chair.

*Dinner* was served at the Fleur-de-lys Hotel.

DR. EDWARD JONES of Caerffynnon, Dolgelly, qualified as a magis'trate for the county of Merioneth on the 1st instant.

## CORRESPONDENCE.

## A LOST MEDICAL SCHOOL.

SIR,—Two Commissions are now sitting, whose duty it is to make better provision for teaching and research in the Universities of Oxford and Cambridge. No one who looks back into the old history of those Universities can doubt that there exists in both Universities a great need for very considerable changes in respect to both teaching and research, and especially in the department of medical teaching and biological research.

In the middle of the seventeenth century, the most important advances in medical knowledge were made in Oxford at the hands of members of the University, who became the founders or early promoters of the Royal Society. It was there that Willis, as Professor of Anatomy, worked out his anatomy of the brain, having as his assistant and demonstrator the young mathematician Christopher Wren, who subsequently became the architect of St. Paul's Cathedral. Wren drew the plates of Willis's work: he was the first to perform a series of important experiments on living animals by injection of fluids into the veins, on which ultimately was based the practice of transfusion. These experiments were done in Oxford.

The close association of the study of medicine with Oxford will be at once recalled to mind, without entering into archæological details, by mentioning the name of Radcliffe, the great physician who founded the Infirmary, who was physician to three sovereigns, and by whose benefaction the Radcliffe Library and the Radcliffe Travelling Fellowships were established. The Regius Chair of Medicine in the University dates from the reign of Henry the Eighth, who was its founder; and to this a Chair of Clinical Medicine was subsequently added. The illustrious Harvey was warden of Merton College, and much of his work was done at Oxford.

It would be idle now, in the present state of the decadence of medical study and biological research at Oxford, to think of finding parallels in University position for such men as Radcliffe and Harvey. As a medical school, Oxford has, within the last twenty-five years, ceased to exist; and it is important, therefore, at this juncture, to notice the steps by which it has been crushed into nothingness, and to protest against the studied neglect by which the Oxford Medical School has been wiped out. There exist now neither lectures on medicine, anatomy, or physiology, properly so-called, or in any sense which can affect the progress of medical science. Prior to the appointment of the present Regius Professor of Medicine, who must be held responsible to the profession for the degradation of the Oxford School, and for the conversion of his office into a sinecure, there were still a few medical students lingering in Oxford. Dr. Acland must be held responsible for having extinguished the genus, of which there no longer remains even a typical specimen to set alongside of the dodo in the Ashmolean Museum. There are no lectures to fatigue the energies of the Regius Professor; and, notwithstanding the delusive notices which from time to time appear in the *University Gazette*, there is no attempt to fulfil the duties of the Regius Professorship of Medicine otherwise than by pocketing its stipend. If the Regius Professor, in the terms of these notices, ever really attends at the Museum to meet the ghosts of the imaginary medical students whom he solemnly cites in print to confer with him on their studies, it would be interesting to know in what soliloquies he indulges, or by what arguments he justifies a course which has led to vacuity and annihilation where once medicine flourished and science found its home.

The Chair of Physiology, founded by the late Commissioners of 1854, has been equally diverted from the service of medical science and of physiology proper. Founded on the remains of the old Chair of Human Anatomy, the present holder, Professor Rolleston, occupies himself and his pupils with any variety of collateral subject, provided that it has no relation to human anatomy and physiology, and cannot

possibly be pressed into the service of medicine. Saxon interments, early ceramic ware, and prehistoric pigs monopolise the attention of the successor of Willis; and it is not surprising that medical students do not consider their wants to be provided for by teaching of this kind.

The examinations of the very few persons who, having studied medicine elsewhere, present themselves for the Oxford degree, are conducted by heavily paid non-resident examiners, a large proportion of whom are not members of the University. It is not in this way that the University of Oxford can fulfil its obligations as an Alma Mater of the highest historic fame and of great accumulated wealth; nor can it regard without shame its Medical Faculty, which has now become a mere simulacrum and the derision of Europe.

The Radcliffe Infirmary, with its two hundred beds, is unused for medical instruction; and the clinical conferences, which are announced with the same pomp in the *University Gazette* as the professorial lectures, are as much an empty sham as they are.

At a recent date, the Medical Faculty of the University of Oxford preserved a nominal existence; and in the *University Gazette* we read—Medical Faculty: Regius Professor, H. W. Acland (no lectures); Clinical Professor, H. W. Acland (no lectures). This, however, probably exposed too plainly the peculiar manner in which Dr. Acland understands his duty to the profession and in which he administers his historic office. The Faculty has, therefore, been removed from even nominal existence, and this professorship appears now only under the head of Physical Science and Mathematics, to which latter department it is probably considered more properly to belong, as having only an abstract existence. The Professorship of Physiology and Anatomy is scheduled under the same heading, the contempt of its incumbent for medicine being thus officially proclaimed.

Under these circumstances, it will be seen that there is a very urgent need for very active proceedings on the part of the Commissioners to restore medical teaching and biological research to their proper place in the University of Oxford.\* The medical profession has a large and direct interest in helping to procure this restoration. The severance of medical study from this great University is a direct loss to medicine and an injury to the profession, which it places almost outside of academic influences at these great centres. It is no less an injury to the Universities. The examples of Edinburgh and Trinity College, Dublin, show how much an University has to gain, as well as to give, by fully carrying out the recognised functions of an University in respect to these higher studies. The meanest of the German Universities does not neglect its duty in this respect as do the two premier Universities of England. It ought not much longer to be tolerated that Oxford and Cambridge should be monopolised in merely pedagogic and clerical interests, and abandon their obligations to the vast national interests which are involved in the academic training of men for the great professions, such as that of medicine.

It might be expected that the General Medical Council of Education for Great Britain would, on this important occasion and in this vital matter, take some earnest step in support of the large measure of reform which is needed to restore the efficiency of medical teaching at Oxford. But, as its President is the Regius Professor who declines to class himself under the Faculty of Medicine, and as the Oxford medical representative at the Council is the gentleman who teaches anatomy and physiology by exhumation and ceramic research, it would probably be more than Quixotic to expect any useful action to be taken by that body.

Professor Acland may be able to explain what are his views as to the extinction of medical teaching in his University, and Professor Rolleston may have unascertained opinions as to the most efficient teaching of anatomy and physiology; if so, it would be consolatory, at least, to be informed of their springs of action. At present, it is difficult, while mourning over the memories of the school which they have extinguished, not to hold them distinctly and personally responsible for something like treason to the Faculty which they represent, and the profession in virtue of whose titles they hold their positions.—I am, sir, yours faithfully,

A MEMBER OF CONVOCATION.

## HARVEY AND HIS CONTEMPORARIES.

SIR,—In connexion with the controversy regarding Harvey's claims to be regarded as the discoverer of the circulation of the blood and of the functions of the heart, it is interesting to meet with any evidence that indicates the state of knowledge on these subjects among his contemporaries, notably among Italians, who are asserted by some to have received the true doctrine from Cesalpino, Servetus, and others, before Harvey taught the results of his researches. Some MSS. have recently been discovered in Hamburg bearing upon the history of medicine in the first half of the seventeenth century, from which Dr. W. Sieveking of that town has been kind enough to send me extracts. One of these is taken from a letter written by Petrus Castellus, Professor of Anatomy and Botany (a combination which appears to have prevailed at that time) at Messina in 1636, to Schlegel, who occupied a prominent position at Hamburg, and had a large personal acquaintance with the scientific press of Holland, England, France, and Italy, of his day.

The extract which follows may fairly be adduced as a further proof that the Italians were not acquainted with the true doctrine of the circulation of the blood before Harvey appeared; and that, if they adopted the term, it was only to meet the requirements of a vague hypothesis. After stating his general adhesion to the views propounded by Hippocrates, with the qualification that he entertains certain opinions not commonly accepted, Professor Castellus goes on to say: "I mean, God willing, to show clearly that Galen was ignorant of the true nature of fevers. But what Harvey has written concerning the circulation of the blood is unknown to me. Neither his book nor his doctrine has reached me yet, so that I cannot understand what circulation he means. I am satisfied that Hippocrates teaches a circle and flow of the blood, which, never resting, and of necessity always moving, if it move, will move not only by a tremulous movement, but in a current, *i.e.*, from place to place; but, as there is no ultimate goal towards which it tends, and where it may attain rest, and the movement is uninterrupted, it follows of necessity that the blood has a circular movement, otherwise it could not go on for ever. Besides, his worship appears, like Harvey, to assign this circulation of the blood as a cause of febrile periods. Nor do I deny that remedies applied to the wrist may sometimes stop a fever, for I have repeatedly seen it. But, in discussing the effect of opiates in my *Antidotarium*" (probably the title of a book), "I have said, as Hippocrates does, that narcotics put an end to fever by inducing quiet in the blood, and that they check the movements of the spirits, or, as it were, congeal them. Possibly Harvey has termed this movement of the spirits the circulation of the blood. Most willingly would I read his works, as his views are unknown to me; but new books rarely find their way to these remote regions."

It is scarcely to be assumed that Castellus had not in 1636 seen the works of Cesalpino, which were published at Venice in 1593; and had he in them discovered anything approaching to the Harveyan doctrine of the circulation, he could not have failed to allude to it in writing to a man who had lived for some time in familiar intercourse with the great students of Italy, and was known as the main advocate and supporter of Harvey's views on the continent.

My correspondent also speaks of the discovery of the MS. sketch of an autobiography of Schlegel, whose admirable exposition of Harvey's views in a small volume entitled *De Sanguinis Motu Commentatio* (Hamburg, 1650) deserves to be better known than it is. The approaching tercentenary anniversary of Harvey's birth renders every authentic contemporary reference to him of special interest; I venture, therefore, to add a translation of a short extract, in which Schlegel speaks of his visit to England.

"I was detained in France by storms, and by the illness of my companion Ering, for ten days; I then crossed the sea in safety, and satisfied my desire to behold the royal town, the essence of all England. I spent four months there without any great advance in my studies, as I devoted myself chiefly to the work of acquiring the English language. I had the opportunity of seeing and making the acquaintance of the following celebrated men. One was *Theodore de Mayerne*,\* the chief physician of the King of England, a man not less successful in curing disease than he was celebrated throughout England and France by his vast erudition, whose learned manuscripts are exclusively handled by the literati of Europe—works which everybody is asking for, and the world wishes to see published. I have also been on intimate terms with *William Harvey*, physician to the king, who, in his published booklet on the circulation of the blood, was the first to display the true course of the beneficent liquid by his ingenious dis-

\* Schlegel calls him Theodosius Mayer Turquetus; and Dr. Munk informs me that "Turquet" was regarded by some as a nickname, though he does not endorse this view.

covery, and thus smoothed the most thorny controversies of our art and the harsh difficulties of the ancients. I have hitherto fought tooth and nail for Harvey's views, have publicly taught them to the students of the schools of France and Italy, and have unfolded this most true and essential doctrine by many demonstrations to medical men."

It is proposed to celebrate Harvey's birth in 1878. I venture to suggest that no better monument could be placed to his memory than the publication of the work which was the first to do him full justice, and which materially aided in making his views known throughout the world. I allude to Schlegel's *Commentatio*, which is admirably written, and shows a perfect appreciation of the revolution in our physiological knowledge which Harvey's discovery was destined to effect.

—I am yours, etc.,  
EDWARD H. SIEVEKING, M.D.  
London, December 1877.

### THE OUT-PATIENT DEPARTMENT OF HOSPITALS.

SIR,—I have read with pleasure, in the JOURNAL of December 15th, an article by Mr. Furneaux Jordan on Hospital Administration, in which he does me the honour to refer to some opinions which I have expressed on the subject of the out-patient department. As I hope shortly, with the aid of the British Medical Association, to bring this matter more into the arena of public discussion, I should be much obliged to you if you would allow me to state concisely and exactly what my views are. In the first place, allow me to say that they apply only to London, and are based on the fact that the metropolis has been consolidated by Mr. Gathorne Hardy's Act into an area under the Local Government Board, who are empowered and directed to found in all parts of it out-patient dispensaries for such sick persons as are unable to pay for medical attendance such a small sum as would entitle them to the membership of a provident dispensary. These Poor-law dispensaries have been founded in all parts of London at the cost of the ratepayers, and are, I believe, admirably organised and superintended by the medical inspectors of the Board. But I believe they are by no means overfull of patients, the old prejudice against Poor-law medical relief being (as Dr. Rogers has often pointed out) still strong among the poor. Nor can we wonder that such a prejudice should long survive when we remember that the state of things which was brought to an end, in a great measure, by your own personal exertions, in company with the late lamented Dr. Anstie. However, it is no longer deserved, and I think I am justified in saying that, in London, no poor person need apply for out-patient medical relief as a matter of charity; for, if he be too poor to subscribe to a dispensary, he can have medical relief of the most efficient nature from the Poor-law dispensaries. Turning to another aspect of the question, I think no one would seriously deny that (speaking still of London only) a great deal of our out-patient relief is superfluous, and a great deal is not efficient. I do not speak so much of the cases of well-to-do persons who are believed to attend out-patient departments. There is no doubt that there is a certain proportion of such persons at special institutions; but such special institutions are often hardly public hospitals in any genuine sense, and we need not here inquire whether all the patients are really gratuitous. There is obviously no public reason why they should be so. But I refer more to the crowd of utterly trivial and routine cases which load our out-patient rooms. We are told that the reason why hundreds of patients are admitted every day at some of these institutions is in order that, out of this mass of chaff, a few grains of wheat may be winnowed; that a few interesting or important cases may be selected for treatment as in-patients. But is this necessary, and is it really done? Mr. Jordan has well pointed out its admitted evil effect in completely destroying the ample field of clinical instruction which the out-patient room ought to afford, but which it now cannot possibly afford, unless the physician or surgeon neglects his primary duty, that of attending to his patients, for what is, after all, as far as the hospital is concerned, only a secondary object: the instruction of the students. I know that some out-patient officers have imparted most admirable clinical instruction to their classes; but it has always, I believe, been done by transferring the great bulk of the routine work to assistants.

Now, the plan I advocate aims at remedying these evils by substituting a small number of well selected cases for a crowd of cases not selected at all; at least, if selected, selected only with reference to their pecuniary condition: quite a subordinate consideration in this matter. I contend that there are no more worthy recipients of hospital relief than the poorer members of the middle classes, but then with the proviso that their medical condition is such as cannot easily be relieved otherwise. I would make the hospital, both in its in- and out-patient department, a consulting institution for those who cannot pay consultation fees exactly as the medical staff are consultants

for those who can; and I would admit no one to the out-patient department (except street-accidents and such like emergencies) but those sent up by some medical authority. I would limit the number of the cases, and would introduce some regulations (which could be easily devised) by which order and despatch in seeing the patients should be secured. There would then be ample leisure for medical and surgical teaching, and a constant supply of material. The absurdity and cruelty of keeping a poor patient waiting for four or six hours, and then scratching a "P" on his paper and serving him out a bottle of useless physic, would be at an end; and it might even be possible to engraft on the out-patient department visits at the patients' own homes, and that instruction in home practice which our present race of students so greatly need. I am quite aware that, as Mr. Jordan too truly says, this suggestion cannot be at once brought into practice, and I agree with him that, for any out-patient reform, the co-operation of the out-patient medical officers is essential. But I believe that it is equally essential to make the general public see that the present system wants reforming, and that, in London at least, all pretence of necessity for the large out-patient departments which are still kept up at our great hospitals has been taken away by the institution of the Poor-law dispensaries. Our London hospitals are great schools of medicine, and many of our out-patient officers are among the best clinical teachers of the day. It is cruel to waste the energies of such men on the caricature both of charity and of medical practice too frequently exhibited in our out-patient rooms.

In fine, sir, my main object in taking up this question is to make the out-patient department a more efficient field for clinical instruction, and I wish to make the public understand that this is as much a public as a professional object. It is too much the habit of laymen to regard the medical school as a "doctor's business", and to direct the whole of their attention to charity. The fact is, that the teaching functions of our great hospitals are quite as much matters of public importance as their purely charitable functions, though the latter are, of course, and must always be, the primary object of the governors; and I am sure no intelligent lay governor could attend the practice of a crowded out-patient room without seeing the waste of teaching power that goes on there, and recognising it as a loss equally to the hospital and the public.

The same principles will apply generally to country hospitals and to those which have no medical school; at least so far as this: that no person ought to be admitted who is not in real want of a consulting opinion, and that every person ought to have a fair share of time and attention given him; but the exact application of the general principles must vary with the arrangements made for providing the poor with out-patient relief gratuitously and by clubs, provident dispensaries, or similar societies.—I am, sir, yours, etc.,  
T. HOLMES.

18, Great Cumberland Place, December 19th, 1877.

### PHYSICIANS' FEES.

SIR,—If any, what kind, and how much, of evidence more is needed to prove the inconsistent variety of modes of practice followed, and opinions held, by the Fellows of the Royal College of Physicians of London, than that shown in the three letters contained in the last two numbers of the JOURNAL? Their authors claim to be "consulting physicians". What is a consulting physician? One who consults with another practitioner of medicine, or one whom anyone consults? Fellows of the College of Physicians of London do both. For fees? Yes. Of what amount? One takes it upon him to see a patient three times for a guinea; another twice for that sum; all for that sum; a sovereign sometimes, it would appear. What kind of cases? Professor Erasmus Wilson is a surgeon; Dr. Tilbury Fox, I believe, is a F.R.C.P. These two have their *specialty* on man's outside; they see women and children also. Mr. Spencer Wells is a surgeon; Dr. — is a physician. These have their *specialty*, in a way, inside; and both are operators. I cannot call the last an operating or consulting surgeon; for he is an operating physician. I take it that—to use that high sounding title—gynaecological physicians and Fellows would not claim rights of practice as surgeons because they turn their attention to women's ills.

Would the operating physician and Fellow of the London College of Physicians excise a tumour from parts external? I think it possible he would, if the terror of outside surgeons and doctors were not within his view. *Honorarium?* No; or honour, one would think, would hold him to a fee hallowed by tradition, as well as to the cherished power (and shall I say pride?) of shutting out the power of recovery of fees.

Does the College of Physicians of London fulfil its mission in hold-

ing to the exclusiveness it professes whilst such *licence* is rampant in it? I trow not. Would an acknowledged *liberty* not be better for the College, the profession, and the world? The world will ever look for the best at the lowest rate, and the highest in rank will not seldom be found the meanest, the most exacting.

Let the College, sir, begin to live again. Let it look back in its records at what Dr. C. J. B. Williams and a few others tried to infuse into its "dry bones" a few years ago. Let it open its gates wide, that the so-called general practitioner may come into its councils openly; for well, and in all truth, can be said to the College, "Of such are some of you".

\* Is the exclusive, the disdainful, the "mulcting" spirit evidenced in the Ex-Censor's letter to be prized? His views are those of a small selfishness, not of a healthy catholicity that would give place, and pelf, and power alone to those of power inherent, and whose work had proved them worthy of all. I should not be surprised if the ex-censor takes guinea fees. Why should all who have held office in the College not ever take less than two guineas? This would seem a step, if taken, in the right direction. The juniors might then begin to live and breathe more freely, and a chance be given them, like the cream, of rising to the top, of being the cream of the profession, highly paid and placed and prized, ere the days come to them when "the keepers of the house shall tremble, and the strong men shall bow themselves".

—Yours obediently,

M.D.

January 1st, 1878.

## THE ORGANISATION OF CHARITY IN HOSPITALS.

VI.

SIR,—In my last letter, I enumerated at some length the principal measures which had been taken during the last seven years by the advocates of hospital out-patient reform, making some reference also to their more important utterances both in the press and at public meetings. Some length of time, however, elapsed between the writing of my letter and its appearance in your columns. It may, therefore, be well for me briefly to chronicle two events which occurred during the interval. I refer to the meeting held in the rooms of the Medical Society (relating to which a leader appeared in your issue of August 4th), and to papers on Out-patient Reform and Provident Dispensaries read to the Public Medicine Section of the annual meeting of the British Medical Association by Mr. Nelson Hardy and Dr. Henry Monckton respectively. The outcome of these meetings was that, at Chandos Street, Mr. Timothy Holmes consented to become Chairman of a permanent Committee whose duty it should be to perfect the system of provident dispensaries, and their co-operation with and affiliation to the hospitals; while the result of the discussion in the Section was, that the Association was recommended to give to a specially appointed Committee full power to promote such changes as might appear necessary, and to investigate and report upon the present system of provident dispensaries in Manchester. I am not aware whether any plan of co-operation between these two Committees has been initiated; but, if not, some such combination will no doubt be at least considered when the season of more active work returns.

I purpose now, if you will permit me, to furnish an account (for which, I regret to say, materials are far from abundant) of the chief reforms that, as a result of prolonged agitation, have been undertaken by the metropolitan and by a few of the provincial hospitals.

In the year 1873, the subject had already, for a period of three years, been receiving considerable attention; and in that year the Committee of the Hospital Out-patient Reform Association had transmitted to fifteen general and to thirty-three special hospitals recommendations for reform, accompanied, as the report stated, by letters addressed to the secretaries of those institutions, asking them to bring the proposed alterations under the notice of their respective governing bodies, and to favour the Committee with their reply. The results of this measure, as indicated by the answers received, were as follows. Eighteen of the institutions made no reply whatever; six simply acknowledged the receipt of the communication; four (University College, the London, the Royal Free, and the East London Hospital for Children) stated that "the matter had been referred to a committee for consideration"; five (Guy's, the Charing Cross, the Royal Infirmary for Women and Children, and two ophthalmic hospitals) stated that "they did not consider any of the proposals of the Association were applicable to their case". One hospital (the Great Northern) stated that "proceedings were in progress which would, it was believed, harmonise with the objects of the Association"; and one (the Westminster) informed the Committee that the authorities there were quite willing to act, provided that others did the same. Of the remaining thirteen, by which alone specific replies were sent to the recommenda-

tions forwarded by the Association, only nine were able to state that they had already put in force the second suggestion; namely, "that a lay officer be instructed to see that the charity be not abused by persons coming who are able to pay".

This *résumé* of the attitude taken by the governing bodies of the London hospitals towards reforms at once so important and so urgently needed is not, to say the least of it, encouraging; and the subsequent history of the agitation can scarcely be said to be more so. Sir Charles Trevelyan, in his paper on Metropolitan Medical Relief, read at the rooms of the Society of Arts last April, has indeed stated that "the special hospitals have to a great extent acted upon the recommendation of Sir William Fergusson's Subcommittee 'that all patients who can afford it should contribute to the support of the hospital'"; and that, "while these hospitals are entirely free to the necessitous poor, a large proportion of them receive, in some form or other, payments from patients who, although they cannot afford the usual professional fees, are above the necessity of purely gratuitous aid". Although, however, this is unquestionably a step in the right direction, as special hospitals are too frequently resorted to without compunction by a class even better able to afford payment for medical attendance than are the more well-to-do patients at the general hospitals, yet, in the absence of any adequate investigating machinery, or any co-operation, for purposes of investigation, with the local Committee of the Charity Organisation Society, it is to be feared that there can be very little just discrimination between those who can and those who cannot afford to pay; and that the reform is, in most instances, very far from thorough, either as to the adequacy of the payments made, the number of those patients required to make them, or the influence of the plan in creating provident habits.

As to the general hospitals, the number of their out-patients is far greater; and, though a few have made improvements and taken measures which, under the circumstances, cannot be too highly praised, there are, it is to be feared, scarcely any in which the reforms can be said to be complete; while those which are pre-eminently the largest, the oldest, and the wealthiest (including St. Bartholomew's, Guy's, and St. Thomas's, with their yearly total of two hundred and seventy-four thousand out-patients), have resisted every appeal, and have refused to make the smallest attempts at reformation.

I believe that the following brief catalogue will be found to include all the hospitals which have consented to consider the question, and will also give a fair idea of the result in the case of each; but, if the information I have been able to obtain from direct correspondence with the hospital authorities and from other sources should, by its publication in your columns, elicit evidence of improvements which have escaped my notice, I shall feel glad to have been the cause of their being more widely known.

The Great Northern Hospital, which at one time attained an unenviable notoriety by giving preference to those patients who could pay a fee of half-a-crown, has set itself to the work of reform with exceptional earnestness. For a time, the out-patient department of this hospital was totally closed—partly, it is said, on account of the abuses observed in its administration; and in December 1875, after it had been reopened, there was read at the Council of the Charity Organisation Society a letter from the Hon. R. Capel (the honorary secretary of the hospital), expressing his strong opinion that a provident dispensary should be attached to every such institution, and that even the dispensaries themselves should take precautions to exclude from the privileges of membership persons able to pay in the ordinary way for advice. Mr. Capel expressed some doubt of the advisability of any entirely gratuitous medical relief at hospitals, and explained that the Great Northern was probably the only hospital in London that had upon its staff an officer whose sole duty it was to register the out-patients, to inquire into their circumstances, and to report regularly to the Executive Committee. In his speech this spring at the house of the Society of Arts, Mr. Capel gave further particulars with reference to the plan adopted; and from his statement, as well as from information supplied by the Secretary of the Great Northern Hospital, it appears that the method pursued is as follows. The names of out-patients having been registered, certain questions as to earnings, social status, number of children, etc., are put to them, and relief is generally given on the occasion of the first application. The officer then visits the homes of a certain percentage of the applicants, and verifies their statements; and the cases are accepted or rejected according to a certain scale of wages. I may here remark, however, that the experience of the Charity Organisation Society in investigating some nineteen thousand cases *per annum* goes far to show that inquiries confined to domiciliary visits do not elicit full and exact information as to the earnings of families.

With reference to the Children's Hospital, Great Ormond Street, I

believe that a final scheme is still under consideration; but, as I have stated elsewhere, the plan pursued at this institution is to relieve all applicants at their first visit, and afterwards to refer them to one of the forty offices established by the Charity Organisation Society in the various Poor-law divisions of the metropolis. Inquiries of a very thorough character are then made with reference to earnings; and, in the absence of special circumstances, all applicants earning more than thirty shillings per week, or receiving Poor-law relief, are excluded. By this system, which has been in operation for some two years, the annual number of out-patients has been reduced from thirteen thousand to nine thousand; while in only 34 per cent. of the cases investigated did the patients find themselves in a position to make a second application. These facts, it may be observed, contrast somewhat remarkably with Mr. Capel's statement that, since the adoption of the plan in force at the Great Northern Hospital, "the number of out-patients has been but very little diminished".

For the Royal Free Hospital, similar inquiries were conducted by the Charity Organisation Society; but, as far as I have been able to ascertain (although the investigation of 641 cases showed only 36 per cent. to be suitable objects of medical charity), no steps towards reform were taken, or are in contemplation.

In the district of St. George's, Hanover Square, the local committee of the Charity Organisation Society has, from time to time, urged upon the authorities of the well-known institution at Hyde Park Corner the importance of out-patient reform; but the only result, as far as I am aware, has been that a very few suspicious cases are referred for investigation to the committee; while the number of out-patients has been limited, and all of them are subjected to some questioning by the secretary or his assistant.

A similar plan has been pursued in St. Mary's Hospital, Paddington, excepting that in the place of the personal interrogation of the patients by a paid officer, there is a weekly examination of the books by a small committee. An investigation of the circumstances of 26 out-patients at this hospital showed (says an article in the *British and Foreign Medico-Chirurgical Review*, January 1875), that only seven applicants were proper objects of charity.

In three of the hospitals that I have mentioned (the Great Northern, St. George's, and St. Mary's) no further reforms are, I understand, in contemplation; and the results of inquiry have even, it would appear, tended to confirm the authorities in their opinion that the extent of the abuses in question has been exaggerated.

At the Charing Cross Hospital, the subject was referred to the medical committee, who reported that the evil was not as grave as had been supposed. It was not, therefore, proposed to alter the existing system, in which there appears to be no other check than the discretion of the person bestowing the letter. The Council admit, however, in their "Notice to Subscribers", that "they had reason to fear that many persons apply for and receive relief who are not proper objects for public charity".

At the London Hospital, in 1874, governors and subscribers were requested to sign a statement, justifying the recommendation of the person applying for medical relief. The tickets also were furnished with a notice, cautioning applicants that their circumstances might, if it appeared necessary, be inquired into.

At the Westminster Hospital, the subject was at any rate very fully considered. Subcommittees were successively appointed, whose reports were far from harmonious; but the chief final results were registration, stricter observance of the hours of admission, and a discretionary power vested in the medical officers.

King's College Hospital has also, I am told, appointed a "Registrar"; but I have been unable to ascertain that any other steps have been taken, excepting that a few cases are occasionally sent to the Charity Organisation Society for investigation. It is right, however, to add, on the authority of Sir Charles Trevelyan, that the number of out-patients, although it has not been subjected to any fixed limit, diminished, under the influence of this revision, from 33,866 cases in 1873 to 21,347 in 1876.

The Royal South London Ophthalmic Hospital has made arrangements with the Charity Organisation Society for conducting investigations, similar to those undertaken for the Children's Hospital by the same body; but I am not aware to what extent the plan has been carried into effect.

Another reform, which is well worthy of mention, has been undertaken by the authorities of the Royal Infirmary for Women and Children. A few months since, when this institution was reopened after enlargement, it became the rule that one penny per week should be paid by each out-patient, and sixpence per week by the parents of each in-patient child; and the sums so collected last year amounted to £120.

The Jewish Board of Guardians, it should here be noted, have in this

matter shown their usual readiness to adopt enlightened views of philanthropy, and, so long ago as 1873, had effected a very thorough reform in their administration of medical charity. Finding, after an experiment of three months, that no hardship had been experienced in consequence of the entire suspension of medical out-relief, and being fully alive to the very serious abuses which had accompanied the former mode of its administration, the Board discontinued it *sine die*, continuing, however, in serious cases of illness, to afford medical attendance at the homes of the patients.

Turning to the provinces, we find that reforms, at least as well worthy of record as are those promoted by metropolitan charities, have been carried out with success in several of the largest country towns, but in concluding a letter, already, I fear, too long, I must content myself with a very brief mention of a few of the more important, reserving for another occasion the specially successful and interesting experiment which has been tried in the City of Manchester.

In Birmingham, dissatisfaction with the evils of the old systems of indiscriminate relief and governors' tickets led, in 1873, to an investigation of a number of Queen's Hospital cases by the agents of the local Charity Organisation Society. In 1874, a subcommittee presented a report on the whole subject, pointing out, as the chief evils of the then existing system, the admission, both as "emergencies" and by subscribers' tickets, of in-patients well able to contribute towards their own maintenance; the abuse of the out-patient department; the indiscriminate distribution of the tickets; their transference, and even in some cases their sale; the triviality of many of the ailments; the discouragement to provident habits; and, lastly, the utter uselessness of this kind of relief to the very poor, unless it be accompanied by a sufficient supply of nourishment. In 1875, therefore, the patronage system was abolished as regards ordinary subscribers, while it was resolved that "governors" also should be requested to surrender their privileges.

The Hambrook Village Hospital and the Stapleton Dispensary (referred to in a letter from Dr. Davey, reprinted in your columns towards the end of 1873) afford instances of institutions which, though scarcely provident in the strict sense of the word, have yet contrived to mitigate the worst evils of the purely eleemosynary system, by requiring weekly payments from their patients.

A reference, however brief, should also be made to the Royal Albert Hospital, Devonport; the out-patient department of which institution has, for some years, been carried on upon the provident principle. It appears that, in 1874, the contributions from members amounted to £509, and those received from other sources to £86; while the medical officers received in the same period £256.

Considering, retrospectively, the whole subject, and comparing these few and too often meagre reforms with the abuses and evils they are intended to combat, I cannot refrain from again expressing a fear that the governing bodies of the hospitals will be exceedingly slow to make any important changes until the subscribers, who form their constituency, can themselves be induced to bring to bear upon them a really effective amount of pressure.

The Provident Dispensary system has taken healthy root in London, and, if only it had room for its growth, might, there and elsewhere, supersede the necessity for any extensive plan of gratuitous medical relief. At present, however, it is overshadowed and dwarfed by the overgrown eleemosynary systems of the hospitals, the Poor-law dispensaries and the free dispensaries, and, until the ground can be cleared, has no chance of healthy development; indeed, the fact that it has not already succumbed in so hard a struggle for existence, affords very encouraging proof of its inherent vitality and vigour. Medical charity, in the meantime, while hindering the growth of medical providence, is itself overweighted by the out-patient system; and only when the various hospitals will voluntarily free themselves from this incubus can they devote their powers, effectively and without drawback, to the noble work of healing and of training healers.

I am, sir, yours obediently,

A MEMBER OF THE CHARITY ORGANISATION SOCIETY.

GREENOCK.—The death-rate for November was 22 per 1,000 *per annum*, 15 per cent. of which was caused by zymotic diseases, and 27 per cent. by pulmonary affections. There was an unusually large mortality from diphtheria, and several deaths from typhoid fever, some of which were caused by infection caught in Paisley. Dr. Wallace observes that the number of cases reported is much in excess of the average in former months, as "nineteen cases of infectious disease were reported by householders in terms of the new Police Act". This is certainly an encouragement for those who believe that there would be but little difficulty in getting householders to report to the sanitary authority the existence of infectious disease in their houses.

## UNIVERSITY INTELLIGENCE.

## UNIVERSITY OF CAMBRIDGE.

**NATURAL SCIENCES TRIPOS.**—The following are the questions in Human Anatomy which were set in the recent examination for the Natural Sciences Tripos at Cambridge. The examination extended over five days.

Describe the temporo-maxillary joint in man and the movements which take place in it. How does it differ from the corresponding joint in the lion? Describe the ilio-cæcal valve in man, and its mode of action. What special purposes does it serve at this part of the alimentary canal? Give an account of the development and descent of the testicle. With what parts in the female do its parts severally correspond? What are the peculiar features of the dorsal part of the spinal column in man (the features in which it differs from the cervical and lumbar parts), and what are the purposes served by those peculiarities? Give the structure and development of the choroid and of the choroidal epithelium in the human eye. Describe the pectoralis major muscle in man, including the disposition of its fibres. What is its action? What relation has the clavicle to its action, and what is its action in animals, as the horse, in which there is no clavicle? Describe briefly the muscles on the anterior or extensor aspect of the leg and foot, and compare them severally with the muscles on the extensor aspect of the forearm and hand. Describe the arch of the aorta in man. What circumstances account for the special liability of this part to overdistension? How is the occipital bone connected with the several surrounding bones? How is it developed? and what reasons are there for regarding it to be serially homologous with the vertebra or not? What are the differences observable by the naked eye in the mucous membrane of the several parts of the alimentary canal, below the pharynx, of man? How do you associate those differences with the functions of the parts? What changes take place in the human brain after birth? Can any reason be assigned for its large size in proportion to other parts of the body at birth? How are the several teeth of the second dentition in man developed? How do they differ from the teeth of the orang? and what relation have those differences to the configuration of the maxilla? Through what parts of the bone has the section in specimen M been made? Name the four canals, painted red and yellow, and traversed by the two bristles. Which of the vertebrae is N? What are O and P? Give the mechanism of pronation and supination of the leg, naming the muscles concerned in it. Compare it with pronation and supination of the forearm. What is the course of the left vagus nerve, and what are its branches? Account developmentally for the peculiarity in the course of its recurrent branch (the inferior laryngeal). Give the anatomy, with the connections and development, of the foramen in the human brain. State the distribution of the nerves to the several muscles in the human arm, forearm, and hand. What relation has the plan of distribution to the grouping of the muscles in harmoniously acting sets? Point out any exceptions to such relation. Describe the membrana tympani in man, and its structure. What are the provisions for regulating its tension, and for maintaining the moisture requisite for its suppleness?—*Practical Work:* Make a dissection of the part before you. Write a description of it, and make any comments upon the disposition of the parts that may occur to you.—There was also an examination *visu voce*.

## PUBLIC HEALTH

AND

## POOR-LAW MEDICAL SERVICES.

## THE PROPER TREATMENT OF APOPLEXY.

SURELY bumbledom is drifting to the bad, or such a case as that recorded in the *Western Mail* of December 17th as occurring at a recent meeting of the Bridgend and Cowbridge Board of Guardians could not have taken place. It would appear that Dr. Bates (who passed his examination thirty-four years ago, is a L.R.C.P., and holds the appointment of district medical officer in the above-named union), was called, in his private capacity as a general practitioner, to attend a man of the name of Guildford, who, it would appear, subsequently died of apoplexy, and who, it was alleged, had not been properly treated by Dr. Bates. This imputation originated with the assistant (whether qualified or not does not appear) of a Mr. Phillips, a general practitioner at Cowbridge, and was brought before the Board by the Chairman at the instance of a Mr. Stacey, who is probably *ex officio*, a member, judging from the fact that it was his first appearance at a Board meeting, and from the pretentious address accorded him in the journal from which we quote. For some time, against the evident feeling of the Board, who clearly sympathised with their medical officer, the Chairman struggled to commit the Guardians to going into the case. In this course, he was backed most strenuously by Mr. Stacey, who, whilst deprecating any personal feeling against Dr. Bates, urged that "he was of opinion that a certain amount of neglect had been shown by the doctor. The question was not one mode of practice as against another; but he would ask them which was the proper treatment of a patient in apoplexy, to do anything or to do nothing?" The Chairman hereupon observed that the Board had not decided whether they would hear the case or not; whereupon the doughty Mr. Stacey said, "I will move that Dr. Bates is not a fit person, if you like"; to which Dr. Bates rejoined that he would grant that "if the charge were true, he was not fit to be their medical officer, but he would have the matter ventilated to the utmost". Ultimately, after a lengthened wrangle, it

was decided, on the advice of the Clerk, that the matter was one which did not come legally under the cognisance of the Board, Mr. Stacey returning again and again to the charge; and, whilst reiterating that he had no desire to injure Dr. Bates, doing his utmost to damage his reputation in every way.

Though it was manifest that Dr. Bates had the support of the majority of the Guardians present, yet we feel he is entitled to the sympathy of his professional brethren in this unworthy attempt to blast his character; and we trust that an opportunity will be afforded him of bringing his would-be defamers to book.

It is time that "outsiders", as Mr. Stacey styled himself, and, for the matter of that, insiders too—who, we assume, are the elected Guardians—should be taught that their position does not warrant them in assailing the reputation of a medical gentleman who may have the doubtful fortune of being one of their medical officers; and we take leave of this subject by quoting the advice of several of the Board, that they hoped the Doctor would "*pitch into*" his traducers, though, of course, only in a strictly legal way.

## POST MORTEM EXAMINATIONS IN WORKHOUSES.

THE following copy of a letter from the Local Government Board has been forwarded to us for publication.

"Local Government Board, Whitehall, S.W.,

"January 1st, 1878.

"SIR,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 14th November last, in which, on behalf of the Council of the Poor-law Medical Officers' Association, you bring under their consideration the question of allowing the medical officers of workhouses to make *post mortem* examinations of the bodies of paupers who die in workhouses.

"I am directed to state that the Board have communicated with their medical officer, and have carefully reconsidered the subject, and they see no reason to alter the views which have already on former occasions been expressed by them upon it. The Board are of opinion that a *post mortem* examination should not be made of the body of a workhouse inmate, except by the direction of a coroner when holding an inquest, or the direction of the Board of Guardians for any especial, urgent, and particular reason which they may deem of sufficient importance to render such an examination necessary, or at the request of the relatives of the deceased.

"The Board also direct me to state that they think that a Board of Guardians would hardly be justified in directing in any particular case that a *post mortem* examination should take place, if the nearest relative of the deceased objected clearly and decidedly to that course.

"The Board, under these circumstances, are not prepared to take the proceedings suggested by the Poor-law Medical Officers' Association, or to issue any minute or regulation on the subject.—I am, sir, your obedient servant,

H. OWEN, junior, Assistant Secretary.

"J. W. Barnes, Esq., Honorary Secretary,  
"Medical Officers' Association, 3, Bolt Court, Fleet Street, E.C.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

ST. GEORGE'S, HANOVER SQUARE.—Dr. Corfield estimated the population at 90,833 persons; and, as the number of births registered was 2,174, and of deaths (corrected) 1,657, the birth-rate would be 23.88 and the death-rate 18.2 per 1,000 population, which are lower than usual. The death-rate of this parish is generally rather considerably below that of all London, as it has the largest proportion of servants to population (about 10 per cent.) of any of the metropolitan parishes. The variations in the death-rates of the subdistricts depend to a great extent on this cause, as in Mayfair it was only 13.00, in Hanover Square 17.97, and in Belgravia 19.46 per 1,000. The death-rate of children under one year was 15.09 per cent. of the registered births, and of persons of all ages from the seven chief zymotic diseases 9.3 per cent. of the total deaths. There were only 2 deaths from small-pox, besides those in hospitals, not returned; but 45 from pertussis, and 47 from diarrhoea. There is not any table of deaths from other diseases, as Dr. Corfield was not supplied with copies of the registrars' returns by his vestry. Dr. Corfield remarks that he received information of 2 only out of the 22 deaths from scarlet fever, and 1 out of the 33 deaths from fever, "showing again the absolute necessity of being provided with the returns of deaths from infectious diseases". The nuisance returns are for the year ending March 31st, 1877, and contain the following singular item: "Inspection of houses after small-pox, 102." How is this to be made to agree with the 2 deaths from small-pox in the district, and 25 cases removed to hospitals? The number of nuisances removed was only 69, against 311

complaints, of which, however, 95 are returned as groundless; so that, unless the 148 houses disinfected after infectious diseases are included in the complaints, there must have been a large number unaccounted for. The slaughter-houses, cowsheds, and bakehouses were regularly inspected and kept in a cleanly state. The non-supply of copies of the district registrars' returns to the medical officer, and the small number of nuisances removed, indicate supineness on the part of the vestry in sanitary matters.

**EVESHAM.**—Diarrhoea was prevalent in this urban sanitary district during the quarter ending September 30th, which is attributed to the feeding of young infants with potatoes and other unfit food. An outbreak of scarlatina is also reported upon, thirty-eight cases having occurred and three deaths. The disease spread rapidly amongst the inmates of some small cottages, in consequence of the impossibility of isolating the patients, as there is no hospital for such diseases, and the healthy children visited the sick. The annual death-rate was 17.1 per 1,000 living.

**WHITECHAPEL.**—In Mr. Liddle's last quarterly report, he refers especially to the schemes which he has brought before the Metropolitan Board of Works under the Artisans' Dwellings Act, and gives the details of the last, which includes houses largely occupied by Jews. Mr. Dyte states that, although the mortality is not so great in that as in other districts, yet the sickness-rate is high, because the Jewish race is naturally long-lived, and the dietary and other sanitary arrangements prescribed by their religion enable its members to battle for a considerable time against adverse hygienic influences. As Dr. Dyte is Medical Officer to the Board of Guardians for the relief of the parish poor, his opinion is entitled to considerable weight. Mr. Liddle also pointed out in former reports that the Jews did not suffer from cholera during either of the epidemics that so severely scourged the other poorer parts of his district. As regards the overcrowding likely to result in other parts through the pulling down of the houses, Mr. Liddle says that he does not think any material inconvenience will be suffered by the poor, as the progress of the pulling down will be slow; and he has seen a large number of houses demolished at other times, when the London Docks were made, without causing distress to those who were displaced. He also refers to the payments by the Bolton Corporation for information as to the existence of cases of infectious diseases, and asks why other local sanitary authorities cannot do the same. There were 609 births and 448 deaths of inhabitants during the quarter.

**BRISTOL.**—There were 958 deaths registered during the quarter ending September 29th, giving an annual death-rate of 21.2 per 1,000. Of these, 276 were of infants under one year old, or 28.8 per cent. of the total mortality, and 15.8 per cent. of the births. The birth-rate was 34.4 per 1,000. The chief causes of the deaths of infants were measles, whooping-cough, and diarrhoea. There were 22 deaths returned from typhoid; but Mr. Davies, the medical officer of health, says he believes some of these were cases of irritative fever. There were 174 cases of "maculated typhus", of which 88 were removed to the Bristol Union Workhouse, where seven attendants on the sick and two inmates were attacked. Mr. Davies approves of their removal; but is it not a great risk to introduce so many cases of typhus into a workhouse? There were 36 deaths out of the 174 cases. He believes that complete isolation of the patient, and disinfection of all infected rooms and clothing, will invariably stamp it out. It appears from the report that Bristol suffered severely in 1864-6, and slightly in 1872 and 1873, through the introduction of the disease in the latter year by an Irish tramp.

**FEVER IN THE CHESTERFIELD DISTRICT.**—The Local Government Board have written to the Rural Sanitary Authority of Chesterfield, in consequence of the recent prevalence of fever within their district, regretting that, notwithstanding the correspondence which took place last year on the subject of fever outbreaks, no infirmary accommodation has yet been provided for infectious and contagious diseases; and pointing out that if the authority had been able to isolate the earlier cases, they might have prevented the further extension of the disease. They conclude by expressing a hope that the matter will receive the immediate attention of the authority.

#### PUBLIC HEALTH MEDICAL APPOINTMENTS.

\*MASON, Samuel Butler, L.R.C.P., appointed Medical Officer of Health for Pontypool, Monmouthshire, *vice* J. Williams, M.D., resigned.  
WALKER, William, M.R.C.S., appointed Medical Officer of Health to the Kirkstatham Local Board.

#### LAWS, CUSTOMS, AND POPULATION.

AN address by Dr. Maurin (*Rapport des Lois et des Mœurs avec la Population*), which was delivered before the French Society of Hygiene in 1877, treats of the evils which have caused the diminution in the natural increase of the French population, and commences with a quotation from J. J. Rousseau, "that the most infallible sign of a flourishing country is the unlimited multiplication of its inhabitants". After enunciating certain truisms as to the effect on a population of its rapid increase, and the contrary, Dr. Maurin expresses his belief that the present outlook for France is sombre, as, although its inhabitants occupy the first place amongst European nations for length of life after twenty years of age, yet it only ranks eleventh as regards marriages, and takes the lowest position as to fecundity. He then asks, "Why should these things be? and what is the influence which the laws, manners, and customs of the country exercise on the progress of the population?" He attributes this longevity after twenty years of age to the fine climate, and consequent ease with which the necessities of life are procured, and to other circumstances which result from the conquests of 1789, the removal of privileges, and the parceling out and division of property.

In considering the causes of the diminished frequency of marriages, in consequence of which France will take two hundred years to double her population against sixty years by Prussia, Russia, and England, and thus be eventually reduced to a second-rate nation, he points out that the large number of unmarried arise from the 100,000 clergy; "18,000 and 90,000" residents in convents, and the large number of domestics and insufficiently paid Government *employés*, making an aggregate of 2,150,000 subjects who are prevented from marrying, at any rate early in life. In addition to these, military service enforces celibacy until thirty years of age on 650,000 men; so that the Government should take some measures to counteract this evil. Dr. Maurin proposes that preference should be given to those applicants for employment under Government who are married and have families, and that some arrangement should be made for the early marriages, at any rate, of some of the soldiers, as, since the increase in the conscription, and consequent late marriages, the number of children in a family throughout the country has been reduced from 4 to 3, and the birth-rate to only 2.68 per 100 of population against 3.68 in England. In support of this, he notices the desire of young married people for a family, and the dislike which those who marry when above thirty years of age have to a large family. He says that rich men over thirty desire but an heir, so that in the richest *arrondissement* of Paris there are only on an average two children in a family, whilst in the poorest there are four. "In the provinces, the farmers, the middle classes, the fund- and land-owners limit voluntarily the number of their children, in order to give rich dowers, and assure themselves of ease in their old age." He remarks, in regard to this, that a restriction of births is to be condemned, because it is opposed to morality, policy, patriotism, the happiness of the family, and the health of the parents. He believes that this evil would be partly remedied by the parents having the power to will their property as in England, instead of its being divided amongst the children in accordance with the present law. He refers to the nervous affections, chronic congestive diseases, dissensions between parents, the keeping of "false homes", and adulteries, to which this system of abstinence leads.

In the second division of his subject, he alludes to the extravagance in dress and luxury by both parents, the desire amongst all classes to eclipse their neighbours, which leads to excessive sums being spent in outside show, and consequent reduction of home expenditure; also to the injurious effects of early smoking, as well as to the excesses and debaucheries of early life, which exhaust the man before he becomes a husband. He says that young women are brought up in such a way that they are unfit for being the wives of honest workmen, and, for want of a marriage portion or a sufficient sum to gratify their desires, adopt, as a last resource, the prostitution of their persons. He also points out in strong terms the injury done to the morals of the young by the licentious romances which are freely published.

One of the almost necessary results of this state of things is that still-born children have increased from three to six per cent. of the total births; because, in the first place, abortion is more frequent, and in the second, that the services of a *sage-femme* is resorted to, who is very unsuccessful in her treatment. Indeed, Dr. Maurin does not hesitate to say that murder often lies hidden under their services, otherwise one death in every four births attended by them, against one in twenty by doctors, could not occur; and he considers that no declaration as to a still-born should be made by any one but a physician. His description of an accouchement under these circumstances is most graphic. As a remedy for this evil, he recommends departmental establishments for

the reception of the newly born, by which he believes that France would gain 30,000 citizens a year, especially as in great cities about fifty per cent. of the children are sent out to nurse, and a large number die for want of supervision of the nurses. He also strongly advises that mothers and those in charge of children should be taught the value of hygiene, and that as many *crèches* as possible should be established. The injury to health caused by the employment of children between six and eight years of age is dwelt upon, as well as the vices developed in young men who emigrate from the country into large cities.

The length to which this notice has already extended prevents us from making many remarks; but we would observe that the population of England and Wales doubled itself in seventy, instead of sixty years as stated, and that the birth-rate assigned to England—viz., 3.68 per 100 population, is somewhat too high. The address, if widely distributed, is likely to be useful, not only in France, but, if translated, in this country also, as it is to be feared that luxury and display are causing here, although to a comparatively small extent, some of the evils discussed by Dr. Maurin.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 20th, 1877.

Ashworth, John Wallwork, Heaton Manor, Stockport  
Cawley, Thomas, Glenely, South Australia  
Clowes, Joseph Smith, Metropolitan Free Hospital  
Gaze, William Henry, Thames Ditton  
Hetherington, George Haynes, Female Lock Hospital  
Meacham, John James, Harpurkey, Manchester  
Reid, William Gladstone, Grove Road, Acton  
Wartenberg, Victor Adolph, Lytham, Lancashire

The following gentlemen also on the same day passed their primary professional examination.

Burnie, William Gilchrist, St. Bartholomew's Hospital  
Costerton, Donald Sinclair, Westminster Hospital  
Culling, William Robert, Charing Cross Hospital  
Haycroft, Charles Henry, Guy's Hospital  
Hitch, Frederick, Guy's Hospital  
Hoskyns, Edward John H., Queen's Hospital, Birmingham  
Lambert, John Speare, St. Bartholomew's Hospital  
Phillips, Stephen Thomas, Charing Cross Hospital  
Priest, James Damer, St. Bartholomew's Hospital

## MEDICAL VACANCIES.

THE following vacancies are announced:—

- CENTRAL LONDON SICK ASYLUM DISTRICT**—Assistant Medical Officer. Salary, £100 per annum, with board and residence. Applications to be made on or before the 7th instant.
- ESSEX LUNATIC ASYLUM**—Second Assistant Medical Officer. Applications to be made on or before the 10th instant.
- HAILSHAM UNION**—Medical Officer for the Parish of Heathfield. Salary, £60 per annum, and fees. Applications to be made on or before the 7th instant.
- HANTS COUNTY LUNATIC ASYLUM**—Second Assistant Medical Officer. Salary, £100 per annum, with board, lodging, washing, and attendance. Applications to be made on or before the 9th instant.
- KINGTON RURAL SANITARY AUTHORITY**—Two Medical Officers of Health. Applications to be made on or before the 7th instant.
- NEWCASTLE-UPON-TYNE INFIRMARY**—Senior House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before February 4th.
- NORTHAMPTON GENERAL INFIRMARY**—Physician. Applications to be made on or before the 9th instant.
- SUDBURY UNION**—Medical Officer for No. 1 District. Salary, £55 per annum, and fees. Applications to be made on or before the 10th instant.
- SUNDERLAND and BISHOPWEARMOUTH INFIRMARY**—Senior House-Surgeon. Salary to commence at £80 per annum, with board and residence. Applications to be made on or before the 24th instant.
- WARMINSTER UNION**—Medical Officer for the Longbridge Deverill District. Salary, £80 per annum. Applications to be made on or before the 14th instant.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*BURD, Edward, M.D., appointed Consulting Physician to the Salop County Prison.  
\*H. Johnson, M.D., resigned.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

### BIRTH.

KILIAN.—On December 30th, 1877, at 49, Harscampstrasse, Aix-la-Chapelle, the wife of \*Paul Kilian, M.D., of a daughter.

### DEATH.

DAVIES, William Abel, M.R.C.S. Eng., at his residence, Castle House, Llandloes, aged 45, on December 15th, 1877.

## OPERATION DAYS AT THE HOSPITALS.

- MONDAY**..... Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.
- TUESDAY**..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY**.. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.
- THURSDAY**... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.
- FRIDAY**..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY**.... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**—Medical Society of London, 8.30 P.M. Lettsomian Lecture by Francis Mason, F.R.C.S.; subject, "The Surgery of the Face".
- TUESDAY**—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. H. T. Butlin, "On the Microscopic Anatomy of the Smooth Tongue (chronic superficial glossitis)"; Mr. W. Sedgwick, "On Maternal Impressions".
- WEDNESDAY**—Hunterian Society, 7.30 P.M.: Council Meeting. 3 P.M.: Mr. Jacobson, "On Supracondylar Amputation of the Thigh by the method of Stokes".
- FRIDAY**—Clinical Society of London, 8.30 P.M. Annual General Meeting. Dr. Althaus, "A Case of Chorea in the Adult Male, complicated with Epilepsy"; Mr. Howard Marsh, "A Case of Severe Hemorrhage after Operation for Cleft-palate, arrested by plugging the Posterior Palatine Canal"; Mr. Holmes, "Sequel to a Case of Excision of the Os Calcis, reported in vol. viii of the Society's Transactions"; also, "A Case of Excision of the Lower Part of the Rectum".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

### EXCISION OF THE ANKLE.

MR. JOHN CROFT writes, stating that, in our report of the meeting of the Clinical Society on December 14th, he is reported as having said that he had not made lateral incisions, but had reflected the soft parts from before backwards. He remarks that he stated that he had used lateral incisions in the three cases to which he referred, and that he had not found it necessary, in order to saw off the ends of the tibia and fibula, to thrust them through either inside or outside wounds; and that he had saved them off by means of a narrow-bladed saw worked from before backwards. He is aware that some modern surgeons have successfully practised the operation under discussion by the anterior incision, and he does not doubt that method enables the operator to expose and examine the interior of the joint very thoroughly. By the lateral method, the joint may be exposed sufficiently well, and the objections which attend the anterior incision are raised against the lateral incisions. He does not wish to be misrepresented as speaking in condemnation of a method of operating concerning which he has never to speak highly.

MR. W. H. PLAISTER.—Your letter has been forwarded to Professor Oscar Liebreich.

### A NEW SYSTEM OF MEDICAL BOOK-KEEPING.

SIR,—Will you kindly allow me to correct an error in your review of this publication, which appeared in the *JOURNAL* of the 15th instant? The "chief advantages" of it are, that you only have to enter once during a month the name and address of each patient in the day-book; that every necessary entry respecting each patient (except the prescription) appears on one line, for the month, opposite the patient's name; that the ledger may be much smaller than usual, may easily be posted at any time, and may be entirely a private book, if so desired. Yours, etc.,  
Cardiff, December 15th, 1877. ALFRED SHEEN, M.D.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the JOURNAL Office or any stated address other than a Post Office.**

#### A SERIOUS GRIEVANCE.

SIR,—Unfortunately, I inherit a name as honoured by the profession as it is well known to the public. Certain druggists and others extensively advertise and sell remedies under the Government stamp, purporting to be made from my late father's prescriptions. As long as the diseases thus announced as cured by the "infallible" remedy are respectable, it is bad enough; but when they descend to lower depths, the association of one's name with them becomes a positive nuisance. I would ask through your columns the advice of any of your readers in this matter. Lawyers seem unable to say whether I have power to stop the traffic, as all turns, in their opinion, upon whose is the property of the prescription. I myself doubt if such a narrow ground for action need be taken: at any rate, it appears to me that the question lies in part in the legality or the reverse of the druggist to make public use of a formula privately at one time submitted to him for preparation: at least, may he not be called upon to show that what he professes to be from a certain physician's prescription is really so, and not evolved from his own brain? Still, assuming that the drugs are really compounded from copies of original prescriptions in the druggist's hands, has he any right publicly to advertise and sell them under the Government stamp, attaching to them the name of the prescriber, together with some fanciful title, and to ascribe to them properties that they do not possess, but that will make them the more attractive to the public? To give greater colour to his imposture, one advertising quack heads his column of advertisements with the crest and motto of the physician upon whose name and reputation he trades. When I am able to prove that such proceedings are doing me harm in my own practice, I presume I should have a hold upon the advertiser in a court of law; but where the annoyance goes no further than having the name one bears attached to compounds which, being guaranteed to cure everything, and being further sold as patent medicines, are by the public not to be distinguished from quack drugs, can nothing be done to prevent it? Twice I have stopped the advertising of drugs by threats of legal proceedings; but whether I could have pushed matters to extremes, I do not know. An all but similar question which I now submit to your readers was tried some time ago in the United States; and if I am correctly informed, it was there ruled that the druggist had no power whatever to employ prescriptions given to him to make up for any other purpose. Is this so in England? Even if there be no law that limits the use a druggist may put a prescription to, can no restraint be put upon a proceeding as nauseous to those unprofessional members of the late prescriber's family as it is likely to be injurious to your obedient servant?  
London, December 24th, 1877. M.B., F.R.C.S.E.

#### ATHETOSIS.

A CONSTANT READER will find a description of athetosis in an article by Dr. W. A. Hammond in the *New York Medical Record* of July 1st, 1873; and in an abstract of the article in the *London Medical Record* for October 8th, 1873. The word is derived from *ἄθετος*, irregular or unarranged; and is applied to a diseased condition characterised by involuntary movements.

#### FRACTURE OF FEMUR: TREATMENT.

SIR,—Mr. H. B. Norman, in a paper read before the members of the South-East Hants District of the Southern Branch, questions the superiority of either Hodge's splint, or the inclined plane with pulleys and splints, over the old long splint and perineal band. Never having used a perineal band, I cannot speak of it from experience; but I have heard no good of it, so have shunned its use. I should like to hear of its comforts or the opposite from some who have had it applied. The pre-eminence claimed, and I think justly, for Hodge's splint, or the inclined plane and pulley treatment, is the greater comfort and comparative ease with which the patient can attend to the wants of nature, with as good results to the limb. That "in the early part of the treatment the perineal band should be daily tightened whilst extension is made from the ankle, must be a discomfort and tend to disturb the patient"; at the same time, the skin over the tuber ischii and groin has to suffer for this daily extension. Dupuytren says: "In many cases, when extension is attempted, the irritated muscles are found more than a match for several assistants." Now, with weights and pulleys, and the bed tilted five inches at the foot, so that the body may act as counter-extension, the patient may be left, the weights doing their work quietly and continuously (morphia or opium being given the first night), the surgeon ascertaining by measurement when sufficient extension is applied, which can be regulated to half a pound. When the length of the limb satisfies, the straps around the short splints may be tightened, and the weight sufficient for retention found out. All this may be done without disturbing the limb. That the apparatus is more difficult to extemporise I do not allow. A reel and wire for pulley, sand or stones in the absence of legal weights, some thin wood or pasteboard for splints, and a bandage or two, are all that is wanted. Billets of wood or books may be used to raise the foot of the bed. Manual strength will not be wanted. It is admitted that by slight omissions, "inadequate protection to the groin, and insufficient padding to the ankle, sloughing occurs and treatment has to be abandoned." Cotton-wool will "lump"; and what can be found soft enough to place against the tender skin of the groin and perineum to stand the accessory extension without endangering these structures or causing discomfort to the patient? In eight cases under my notice, treated with weight and pulley, no discomfort was remarked on, and all did well. One was an ununited compound fracture of twenty-five weeks' standing; the wounds had healed at the end of seven weeks; the long splint had been applied twice, and there were three inches and a half of shortening. This patient was sent out with a firm limb, of one inch and a quarter shortening, and has since gone to sea. All the patients at the end of a month (average) had a Pavianian splint applied, and were allowed to get up. The average shortening was half an inch.

The cases I have seen treated with Hodge's splint looked wonderfully comfortable, and the degree of mobility allowed the patient was astonishing; but the good results, as attested by Mr. Farrant Fry, show that no harm takes place.—I am, yours, etc.,  
LATE HOUSE-SURGEON.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### ACUTE LARYNGO-TRACHEITIS (CROUP) TREATED BY AFFLICTION OF ICED WATER.

SIR,—Being of opinion that the term "croup," as pointed out by Dr. George Johnson and others (*Gide BRITISH MEDICAL JOURNAL* of September 18th, 1875, p. 355), is unsuitable as applied to a form of disease, I prefer to record particulars of this case under a term which I believe more correctly defines the pathological condition. The treatment adopted is that recommended by Professor Porter of Dublin, which to thoughtful minds cognisant of the true state of matters, the "bugbear" of infantile disorders will be found, I believe, to possess such an amount of rationality as to supersede all other remedies, such as the administration of medicine or the resort to tracheotomy. I may say that I adopted this line of treatment from my own deductions; but on looking up records of "croup," I find that the gentleman mentioned has forestalled me in recommending it, so I can merely recite this case as corroborative, in a marked and satisfactory manner, of its beneficial effects.

On Friday, December 14th, I was called upon to visit a boy eight years of age suffering from "croup," or, to adopt our nomenclature, "acute laryngo-tracheitis, with 'croupous' respiration." He had been at school the day before, though slightly ailing, but had gradually become worse. I had come provided with an emetic mixture of sulphate of zinc and ipecacuanha wine. This was administered twice, at intervals of ten minutes, until vomiting was produced. A bladder had been provided, and, being conveniently filled with ice-cold water, was applied to the throat and upper part of the chest, kept in position well under the chin—the child, of course, being in the prone posture. The child, who naturally objected at first to the cold, became quieter, and in a short time fell apparently into a doze. The respiration, which had been harsh and crowing, gradually became less so; the cough lost somewhat its singing sound; and the skin, which had been hot and dry, became cool and moist. I stayed for two hours in the house, and when I left, I gave instructions that a large warm poultice was to be applied for an hour in place of the bladder, and then the iced water to be again reapplied, alternating so each hour until my return. In about ten hours I came back and found everything progressing favourably. The child is now well; and I believe the result might have been very different, at any rate, the chances of recovery much diminished, had that treatment not been adopted.

In conclusion, I may perhaps be permitted to express an opinion as regards the relations between croup and diphtheria, in view of the fact of a committee having been appointed by one of our leading societies so long ago as 1875 "to examine into the relations existing between the diseases commonly known respectively as 'membranous croup' and 'diphtheria'." I am inclined to the opinion that the former may be accurately defined as simple acute inflammation of the larynx and trachea (laryngo-tracheitis), terminating in the usual products of inflammation, a mucopurulent secretion—in some cases, possibly a fibrinous exudation; whilst the latter partakes more of the nature of a specific inflammation of the mucous membrane, not confined to the laryngo-tracheal or respiratory track.—I am, sir, your obedient servant,  
J. MAUNSELL, M.D.

Sheffield Road, Barnsley, Yorkshire, December 17th, 1877.

#### INDIAN GUIDE WANTED.

SIR,—In reply to Mr. Lennox Browne's inquiry in your *JOURNAL* of December 22nd, I would suggest his perusal of a small volume entitled the *European in India*. I think it would fulfil all his requirements. I do not know the publisher, but think I paid about five or six shillings for the copy I had.—Yours, etc.,  
Sowerby Bridge, December 24th, 1877. JAMES ELLIOTT.

\* Surgeon-General Francis, M.B. (Sutton), has, we are informed, in course of preparation a Guide which is intended to supply the want to which Mr. Lennox Browne has drawn attention.

#### MALPOSITION OF THE TESTIS.

The descent of the testis has always been looked on as an interesting phenomenon. At the seventh month of fetal life this organ passes into the internal inguinal ring, and at the eighth month it is found in the scrotum. In this descent, there seems little reason to doubt but that the gubernaculum plays an important part, and any deviation from the natural position of the testicle will probably depend on some structural abnormality or premature change in this areolo-muscular substance. This is a malformation which occurs perhaps more frequently than is generally supposed; for as it does not prevent procreation, either nothing is said about it or it may altogether be overlooked. Several interesting cases have lately been recorded in the *BRITISH MEDICAL JOURNAL*. In one of these, both testes were absent; whilst in the other three, a hernial protrusion was present in each. From this coincidence, it might be concluded that a hernial protrusion always occurs; but I may perhaps be allowed to state that I have examined three individuals having a malposition of testis, without finding a hernia to exist in any.—G. R. GILRUTH, Edinburgh.

#### APPLICATION OF FLUID CAUSTICS.

SIR,—Permit me, through your *JOURNAL*, to suggest the following mode of applying nitric acid, or any other fluid matter, to wounds from dog-bites, etc. Procure a glass tube (the sizes Nos. 7 or 8, of common wire-gauze, will do), tapering at one end. On introducing this tube into a volume of liquid, the liquid will ascend in the tube as high as the body of the liquid; when, by placing the finger on the upper end and closing it hermetically, it may be conveyed and introduced to the bottom of the wound. By blowing down the tube immediately before, and while withdrawing it, the fluid should reach every part of the wound. A syringe might do. Probably the tube ought not to be too sharply pointed.—I am, sir, yours faithfully,  
Neath, December 8th, 1877. JOHN RUSSELL.

#### CAUSTICO DI LONDRA.

IN reply to the inquiry of Dr. Ruata of Padua (*BRITISH MEDICAL JOURNAL*, December 22nd, 1877), Messrs. Bullock and Co. of Hanover Street send the following note:—"Pasta Londinensis (London Paste), Dr. Mackenzie's. R. Caustic soda, unslacked lime, of each equal parts; reduce to a fine powder in a warm mortar, and mix intimately. Keep in well closed bottles, and when required for use, take as much as is sufficient, and make into a paste with water.—Use: Recommended for destroying enlarged tonsils or the elongated uvula, where treatment with guillotine or scissors is objected to.—Note: This preparation resembles the Vienna paste, but is preferable, in consequence of its being less liable to spread beyond the limits of application. Soda being used instead of potash, and water in place of alcohol, the preparation is much less painful."—*Throat Hospital Pharmacopæia*, edited by Dr. Morell Mackenzie.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### QUININE IN CATARRH.

E. W. writes to ask whether the virtue of quinine as a preventive of ordinary catarrh is generally known, or whether he must regard himself as exceptionally constituted; and remarks that, though enjoying good health, he was always susceptible to colds, and never got through a winter without several, while since he has taken a small daily dose of quinine (one grain) he has been virtually free, though sometimes exposing himself to risks that would previously have been highly imprudent.

#### THE CATERHAM ASYLUM.

DR. ADAM (Caterham).—We should be very glad to comply, if possible, with our correspondent's wish; but to publish the documents submitted on both sides would involve a very considerable expenditure of space, and of course we could not publish the documents on one side without publishing those on the other; and to this, we fear, there would be no end. We have carefully considered the statements submitted by Dr. Adam and Dr. Curtis on the one hand, and Dr. Rogers and his friends on the other hand, and have expressed briefly our conclusions, derived from the perusal of those documents. Even if no Government inquiry be held, what has happened, with our comments thereon, will probably not be without salutary influence both on local boards of guardians and the authorities of metropolitan district asylums, for we are inclined to think that there is room for amendment on both sides. The patient in question should have been sent ten days earlier, and the medical officer of the Caterham Asylum must learn that the character of other professional men must not be assailed to further the administrative views of any public body.

#### UNSEAWORTHY SEAMEN.

SIR,—As the agitation concerning the unseaworthiness of ships seems to have proved beneficial to sailors in general, it may not be out of place in these columns to say a few words on the subject of the unseaworthiness of seamen as regards venereal diseases. As the condition in which a great many sailors proceed to sea may not be generally known to your readers, I should like to state a few facts as having come under my own observation within the last few months at the Liverpool Dispensary for Seamen. Out of a large number of sailors who apply there for treatment, I am sorry to say that a great many proceed to sea in a shocking state of disease. To give an idea, I quote the following facts as having occurred within the last month.

Case I applied for advice on November 24th, suffering from acute phimosi, purulent discharge underneath the prepuce, and indurated glands of both groins. This man proceeded to sea on November 28th.

Case II applied for advice on November 27th, suffering from six ulcers of the corona glandis. He also proceeded to sea on November 28th. (Cases I and II were shipmates.)

Case III applied for advice on December 1st, suffering from a well marked indurated sore, of the size of a sixpenny-piece, situated on the under surface of the prepuce, having all the appearance of the "parchment induration" described by Ricord, accompanied by indurated glands in the left groin. This case only remained under treatment until December 13th, as he went to sea on the following day. This was very mortifying to me, as the disease was beginning to yield to treatment.

Case IV applied for advice on December 4th, suffering from a copious papular syphilitic eruption and sore throat. On the following day he also sailed.

I may mention that these four sailors' ships were unprovided with a surgeon. I could give numerous instances of seamen who have gone to sea suffering from acute gonorrhoea and buboes (and my colleague Mr. Frederick Lowndes informs me that similar cases under similar circumstances have come under his observation also), but the foregoing cases suffice in a measure to show that the present condition of our seafaring population is in a very unsatisfactory state as regards venereal diseases.—I am, sir, yours obediently,

A. BERNARD, M.D.

Liverpool, December 15th, 1877.

#### PETRARCH ON MEDICAL PRACTICE.

PETRARCH, who is reputed to have been accustomed to seasonal venesection, is known to have had a violent feud with the physicians of his time; not, as he protested, against physicians as a body, but against pretenders. His antipathy seems to have arisen in this way, as he himself relates in a letter to Francesco da Siena, a famous physician (*Senilis*, L. xv, Ep. iii). The Pope Clement VI being taken ill, Petrarch sent to him, to warn him against physicians; not against the whole body, but against many, and reminded him of the man who had caused to be inscribed on his sepulchre "La multitude de medeci mi ha ucciso" (I have been killed by the multitude of physicians); and he then recommended the Pope to have not even two, but only one physician, who should not merely be eloquent, but learned and wise. The messenger not having made himself intelligible, the Pope begged Petrarch to send him the message in writing; which order was obeyed. The physician of the Pope, who saw this letter, was indignant, and made a bitter reply; hence the feud. In a letter to Boccaccio (*Senilis*, L. v, Ep. iv), in which he describes the vanities and pomps with which the physicians of the age appeared in public: in purple garments, precious rings, and gilt spurs; he says jocularly that very little fails them to arrive at the solemn honours of a triumph; though it is true there are not many among them who can boast of having killed their five thousand men, the number necessary for a triumph; but what they lack as to quantity is made up in quality. Since the one slew their enemies, the others their fellow-citizens; the one slew armed men, the others those in civil garments. Then proceeding to ridicule what he calls their impostures, he states that he had himself heard of three celebrated physicians of his time, one of whom confessed sincerely, that if a hundred or a thousand men of the same age and complexion were taken with the same disease, and one-half were entrusted to the physicians of his time and the other half were left to themselves, more of these last would recover than of the first. Another, who was interrogated by him as to how it was he did not use the same regimen that he prescribed to other people, replied that if the living of a physician were similar to his counsel or his counsel to his living, he would lose either his health or his money. And lastly, the third, who had acquired great celebrity, being asked why he did not follow medicine, answered that he was not so wicked as to delude people with so deceptive an art. He relates in the same letter of an old physician of Valesia, who was summoned to Milan by Galeazzo Visconti, to cure him of the gout, with the promise of three thousand five hundred golden crowns, the expenses of the journey, and a magnificent reception. "The same day on which he arrived, I was dining with Galeazzo, when a courier came beforehand to announce his arrival. Galeazzo was rejoiced to the utmost, and commanded that he should be met, and received, as was the custom, with rejoicings and pomp. They sent out a cortege, servants,

and horses, and a charger, upon which he was to mount, as tried by myself on other occasions, whither than snow, swifter than the winds, tamer than a lamb, and freer than a mountain. On this the German Galen entered Milan amidst a great concourse of people, who looked on with wonder, and hoped now to see the dead arise. Already the messenger whom he had sent beforehand had, on the authority of the physician, ordered to have ready fresh eggs and I know not what other things, as was usual, to make a beverage for the sick man. At hearing this all were struck with wonder, and some thought he was a divinity; but I was grieved to observe the rashness of the man who, for such a patient, whom he had never seen, should thus prescribe remedies for his case. Having in the meantime set out for Pavia, I know not what he did or ordered on the following days. But I know that Galeazzo immediately began to get worse than usual, and not long afterwards the physician, baying not only lost all hope to cure him, but even the impudence to promise it, said that by art he could not do what he had promised; but that instead it was necessary that he should consult certain books of magic that he called sacred; since in these rested the last hopes of cure. He set to work to search, I know not in what part, and perhaps he did not know himself; but the hopes of all, and especially of Galeazzo, at once vanished. Thus that great fame, those strange expectations, that prurient desire to find a cure, is departed to end in magic." In a letter to Pandolfo Malatesta, dated May 28th, 1379 (*Senilis*, L. xiii, Ep. viii), Petrarch says: "I have been attacked by a violent fever, to which I am now accustomed. The physicians arrived by command of the master (Francesco da Carrara) as if they were friends. After having for long, according to custom, debated among themselves, they decided at last that I should die in the middle of the night, and night had already commenced. You see what little of life remained to me, if what these Hippocratici dreamed were true. But I am constantly getting more confirmed in the opinion which I had formed of them. They said that the only remedy to extend my life a little longer was to bind myself with certain strings so as to prevent sleep, and, by that means my life might be extended to the morning. This was too great a price for so small a benefit, while it was certain that to thus deprive me of sleep would be equivalent to killing me. These directions were not followed out; for I have always begged of my friends and commanded my servants that they should not do anything that was ordered by the physicians; but, if they must do something, they should do the complete contrary. Thus I passed the night in a profound sleep, similar, as says Virgil, to a composed death. What then? I, who ought to have died in the middle of the night, when the physicians paid their visit in the morning, perhaps to assist at my funeral, found me writing. They were astonished to see me, and could only say that I was a wonderful man."

#### MEDICAL ASSISTANTS.

SIR,—Will you kindly allow me a corner of your valuable JOURNAL regarding the duties involved in medical assistantships? Is it customary for medical assistants to act the part of slaves' assistant in addition to their professional duties? Is the honorary appointment of door-porter attached to all assistantships? and does this appointment serve as an introduction to patients, by showing the assistant's ability and importance? Does time for study mean perpetual motion in door-keeping—viz., motion in proportion to the extent of the practice? Is door-keeping to an assistant a torture or pleasure? Is it recognised as part of the curriculum at the College? or do the patients consider it a gentlemanly occupation? Why do the majority of assistants who hold this extra appointment take all available opportunities of outside amusement in preference to the inside torture of studying from Nature the mechanism of the muscles in motion? Is the comfort of an assistant ever studied? or has inside comfort any control over an assistant's (often unnecessary) outside wanderings and its consequences? Is door-keeping a sufficient inducement for an assistant to spend his leisure time within? If seclusion from servile work in the absence of professional duties be a comfort to a principal, would it be injurious to an assistant? Will some victim be good enough to give a novice a little information concerning the art of surgery, door-keeping, or any other unprofessional or degrading torture to which assistants are subject? Hoping I have not encroached too much upon your limited space,—I am, yours, etc.,

December 1877.

JANITOR.

#### AMATEUR PRESCRIBING.

A LAUGHABLE instance of the curious ideas that haunt the minds of the clever amateur physicians one constantly meets with is related in *Belgaradi* by Mark Twain. He declares that a skipper in the North Pacific has lost faith in his medicine-chest, and complains as follows: "There is something rotten about this medicine-chest business. One of my men was sick—nothing much the matter. I looked into the book, and I said, 'Give him a teaspoonful of No. 15.' I went to the medicine-chest, and I see I was out of No. 15. I judged I'd get up a combination somehow that would fill the bill; so I hove into the fellow half a teaspoonful of No. 3 and half a teaspoonful of No. 7, and I'll be hanged if it didn't kill him in fifteen minutes. There's something wrong about this medicine-chest system that's too many for me!"

#### INFLUENCE OF MARRIAGE ON EPILEPTICS.

SIR,—I can call to mind the cases of two men who were under my care about two years ago, who had been the subjects of fits at intervals for some years, who had recovered to a very great extent, and in both cases were anxious to marry. I was asked, What would be the effect of marriage on their condition? and I had to confess that I could not advise them with any certainty. One of these men married at once, and I saw him as late as four or five months ago, when he told me that he had never been better in his life, and had "no fit since marriage." The other man was more cautious; and, having satisfied himself that conjugal duties were not injurious to his health, married, and has retained his health, without there having been any relapse quite recently.—Yours faithfully,

Charlton, Kent, December 16th, 1877.

HERBERT L. BERNAYS.

MR. A. C. TUCKER's letter has been referred to the General Manager.

#### DIVISION OF LABOUR IN SCIENCE.

ST. GEORGE MIVART remarks on this subject: "The principle of the division of labour renders necessary the application of one man's almost entire energy to a more and more restricted field of scientific labour. Only intellectual giants can now hope for eminence in widely remote areas of study and research. To take an example from one science, men have not only almost ceased to be general zoologists, and become ornithologists, entomologists, etc., as the case may be, but we hear now of lives being devoted to the study of small sections of natural orders, and that this naturalist is a *Carabidist*—that is, devoted to that family of beetles termed *Carabidae*, and that a *Cuculionist* (devoted to the long-snouted beetles termed *Cuculionidae*), while a German naturalist has even published a quarto volume, with large plates and numerous tables, the whole being devoted to the anatomy of the lower part of the hindmost bone of the skull of the carp!"

MR. ALFRED W. MOORE should apply to a chemical source for the information which he seeks.

## MEDICAL REGISTRATION IN GREAT BRITAIN.

It would appear from a recent legal interpretation of the letter of the Medical Act regarding medical registration in Great Britain, that the system is by no means perfect. In a recent case of flagrant quackery, based upon a bogus American diploma, it was impossible to convict the defendant, because it was not distinctly stated in the wording of the Act that any one whose name did not appear on the *Medical Register* was not legally qualified to practise medicine or surgery. The requisite amendment is now strongly urged, upon the plea that the public have a right to be protected from fraud. The object of the Medical Act was principally to create this *Register* of well qualified practitioners, thereby offering to the public a ready means of discrimination between those who had undergone a regular course of instruction and those who, without any real ground, passed themselves off as qualified medical men. The Medical Council is the court of arbitration, and has certain discretionary powers, which do not, however, extend to the acceptance of colonial degrees. In the proposed amendment, it is suggested that cognisance be taken of such degrees, with a view of showing fair play to all well educated foreigners who may wish to settle in Great Britain. This is a liberality of opinion in keeping with the spirit of the age, and should be emulated by all civilised countries. Thus far, thanks to the bogus diploma traffic in this and other American cities, the very name of the American medical diploma is associated in the English courts with the worst of frauds.—*New York Medical Record*.

## AN INDIAN QUACK PILL.

A CORRESPONDENT has sent us a copy of a handbill which was given to him some time ago in Bombay. It is headed "Bapoorow Raghoonath Nagpoorker's Pure Drug made Tonic Pills. Do not dissolve if boiled in milk or water for a number of days". The bill states that "These pills are prepared from a mixture of various drugs. Their curative effects are various and wonderful. They purify and produce blood, increase strength, promote digestion and circulation of the blood, improve the appetite, speedily restore health, render the complexion florid, and keep the mind always cheerful. They are also a powerful and speedy remedy against Liver-complaint, Rheumatism, Giddiness, Headache, Shivering of the hands and the body, weakness of the joints, spitting of blood, consumption, General debility, impaired nutrition, female complaints and the diseases of children. Women in confinement" (i.e., the Zenana) "using these Pills are protected from Rheumatism, and are freed from Menstrua or (Fleur Albis). To newly delivered women these Pills are very useful. . . . If either men or children are affected with Dismissis seminis these Pills cure it without fail", etc. The pills are to be used for forty days according to the following directions. "Every day the Pill with the silken covering should be boiled in Milk with a little quantity of almond kernels, till half the quantity of the Milk is boiled away. The Milk is then ready for use. The Pill should be taken out of the Milk, washed in cold water, exposed to the air till it dries and assumes its original hardness, and then securely kept for future use. The Milk thus prepared is to be drunk after supper, but about an hour before going to bed. A little sugar may be added to the milk at the time of drinking it." The pills are sold in three varieties, at prices of five, ten, and twenty rupees each; and are also lent on trust for a fortnight at fixed rates. Several testimonials, of the usual character, are appended: they are signed by a "Chemical Analyser", a native Government Magistrate, an officer of the Government Telegraph Department, a Railway Guard, and other persons. One Native Gentleman furnishes the following specimen of literature. "Certified that I sincerely and faithfully acknowledge that on the time of the examination of the effects of medicine what Mr. Bapoorow has given me in the way of a globe covering with a silken cloth and ordered to drink it in milk, has given me much good, and I hope that every one who wished to buy can trust on my writing. I am, here, Zahoorul Huj, Medical Officer."

## URINARY TEST-TUBE.

SIR,—Dr. Batten's invention of an urinary test-case, to which practical effect has been given by Messrs. Salt of Birmingham, is at once elegant and ingenious. The want of a testing apparatus, easily and safely portable, has long been experienced, and Dr. Batten has, to a great extent, supplied this want. It has struck me that its efficiency might be much increased by the addition to the case of a small spirit-lamp. Dr. Batten mentions in his letter of October 18th, that a candle or ordinary lamp may be employed in heating the tube containing the urine, care being taken that it is inserted in the blue flame. Now, it is not always that a blue flame can be discerned on a candle, and with the utmost care the test-glass is apt to be blackened. I suggested the above addition to Messrs. Salt, who kindly adopted it, and have manufactured for me a case with this improvement. The only objection that could be urged to this addition is a small increase in the length of the case, necessitating its being carried in the inside pocket of the coat instead of that of the waistcoat. I think the advantage of the combination with the test-apparatus of a smokeless lamp more than commensurate with the questionable inconvenience of a transfer from the smaller pocket to the larger.—I am, Sir, yours, etc.,  
MALDON, DEC. 11TH, 1877. GEO. PARKER MAY, M.D.

## AN ADVERTISEMENT.

THE *Auckland Times* of December 14th has the following singular advertisement:—"Dr. Arnold (for many years assistant with the late Dr. Canney) having removed to 13, Low Tenter, takes this opportunity to state that he will give advice free every morning (Sundays excepted) from nine to ten o'clock to the poorer classes in the town, and on Thursdays and Saturdays from 2 to 5 p.m. to country people. Those in the town who are unable to attend the surgery through illness will be visited free of charge. Medicines and surgical appliances, where required, will be supplied at the lowest possible charges."

## A NEW TREATMENT OF CANCER.

SIR,—The enclosed advertisement I have cut from a local religious periodical. The advertiser's name appears in the *Medical Register*. Surely this new method of treating "cancer and tumours" ought to be known.—Yours, etc.,  
15, Bury New Road, Bolton, Dec. 11th, 1877. J. JOHNSTON, M.D.  
"Cancer and Tumours Cured by an entirely new and Painless Process, without the knife. Totally different to any treatment at present adopted. Pamphlet 12 stamps. Particulars, stamped envelope. Edwin W. Mabone, M.D., M.R.C.S. Eng., Lynton House, Mildmay Road, London, N., Physician to the Home for Reclaimed Females, the Clapton Orphan Asylum, etc. Under this treatment, many cases pronounced hopeless have recovered."

## PROFESSIONAL INCOMES IN AMERICA.

To pass the examination required to enter the army or navy demands a very thorough professional, and also an extended general, education; and yet the salaries of medical officers are hardly adequate to support a very economical family in a manner corresponding to the social position of a professional man. Outside of the army, in the rural districts and country towns, it is a decidedly desirable practice that yields three thousand dollars a year in actual money; and so far as our observation goes,

it must be a very exceptional country locality where a physician can collect over five thousand a year. The work such a practice entails will task him to the uttermost. In cities, it is of course otherwise. There are physicians in all our large cities who take in ten thousand and fifteen thousand dollars a year: we could name a few in this city and New York who are popularly credited with practices returning twenty-five thousand to thirty thousand dollars a year. One year with another, there are exceedingly few in the United States who exceed this. Some eminent surgeons may possibly do so, but they could be counted on the fingers of one hand. But these are the rare prizes. The vast majority of city practitioners fare no better than those in the country; and it, as a rule, requires much longer to get to the point where they "make a living", because living is costlier and competition closer. Many physicians have some outside business in which they are interested; others have a patrimony which helps them out. Without these resources they would starve.—*Philadelphia Medical and Surgical Journal*.

## AN APPEAL.

MR. SCARNELL wishes gratefully to acknowledge the receipt of the following amounts sent in answer to his appeal, which appeared in last week's *JOURNAL*: A Friend, £5; A Friend (of Birkenhead), £2; Dr. Raaking, £1; W. D., £1; Anonymous, 10s; Dr. Cassell, 5s; B., 5s.—1, Frederick Place, Penton Place, S.E.

SIR,—Permit me to express a hope that Mr. Howard Marsh will publish in book-form his admirable Lectures on Hip-Disease in Children.—Yours, etc.,  
CASHEL, IRELAND. THOMAS LAFFAN.

A STUDENT.—The recommendation that candidates for diplomas should be required to produce evidence of having attended class-examinations from time to time, does not appear in the present code of recommendations of the General Medical Council. We believe, however, that the omission does not arise from any change of opinion on the part of the Council as to the value of such examinations, but from the matter being one of detail belonging to the regulations of the examining boards.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Masbro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; etc.

A New System of Medicine, entitled *Recognisant Medicine, or the State of the Sick*. By Eholanath Bose, M.D. London: J. and A. Churchill. 1877.  
*Principles of Rational Therapeutics*. By Eholanath Bose, M.D. London: J. and A. Churchill. 1877.

# LECTURES ON THE INFECTIVE PROCESSES OF DISEASE.

*Delivered in the Theatre of the University of London.*

By J. BURDON SANDERSON, M.D., LL.D., F.R.S.,

Professor of Physiology in University College; and Superintendent of the Brown Institution.

## LECTURE III.—*Pathology of Septicæmia.*

AFTER describing the phenomena of septicæmia, so as to enable you to have before you a sufficiently well defined picture, first, of the effects which show themselves in animals in consequence of a dose of septic poison, and, secondly, of the corresponding symptoms in man, I proceeded to discuss the pathological questions relating to the septicæmic state under two heads; viz.: 1. The efficient cause of septicæmia—the septic poison; and 2. The nature of the pathological process. In the last lecture, I concluded what I had to say to you on the first of these subjects; viz., the genesis of the septic poison, and the important part taken by bacteria in its production. I have now to ask your attention to the nature and effects of the changes which it produces in the circulating blood.

In order that we may be in a position to enter on the study of this question advantageously, let me recall your attention to the main features of septicæmia in animals and in man, as I described them in previous lectures. We saw that it is characterised by (1) the loss of muscular strength, particularly of the heart and respiratory muscles; (2) by the marked tendency which exists to the development in various internal viscera, but more especially in the lungs and in those which send their blood to the portal vein, of a congestion, which has as its concomitant results capillary stasis and hæmorrhage and diffused infiltration of the affected tissues; and finally (3), by brain-disorder and fever.

The most important matter for consideration is that of the relation between the altered condition of the blood and the other phenomena. If, as has been suggested, the alteration of the blood-corpuscles be the primary fact, how does this change in their condition produce the other disorders? May it not be that some of these disorders are due to the immediate action of the poison on the nervous system, or on the tissues generally? I shall endeavour to show that, so far as concerns all those phenomena which belong to the circulatory system, we have good reason for attributing them to the pernicious influence exercised by the poison on the blood-corpuscles; for, in studying experimentally the pathological disturbances produced by agents which can act only in this way—i. e., by disintegrating the blood-corpuscles—we find that the morbid changes produced by them in the organs of circulation entirely resemble those of septicæmia. I found this statement on certain important observations which have been made very recently by Dr. Köhler,\* at the suggestion of Professor A. Schmidt of Dorpat, whose name is well known to us all in connection with his investigations as to the coagulation of the blood. Let me first relate to you the facts as they stand. What has been observed is as follows. If, in a dog, a couple ounces of blood be taken from the femoral artery and allowed to coagulate, and, after the lapse of twenty minutes or so, the clot be broken up and kneaded with the fingers, and the carefully strained blood be reintroduced into the femoral artery of the opposite side, so as to mix very thoroughly with the blood-stream before it reaches the heart, it is found that this apparently harmless procedure is attended with the gravest consequences. In ten minutes, or even in a shorter time, after the injection, the animal is collapsed, as if poisoned; the pupil is dilated; even reflex action is much diminished; the heart beats irregularly, but strongly; and the respiration is difficult. These more violent symptoms pass off; but soon alvine disorders resembling those which I described to you in my first lecture present themselves. First, normal defæcations are passed with more or less tenesmus; then follow liquid, mucous, and sanguinolent evacuations in rapid succession; the discharges become more and more bloody; and the animal, if not killed, dies in a state of complete prostration. If the examination of the body be made immediately after death, so as to avoid post

mortem changes, appearances present themselves which any person acquainted with the signs of septicæmia would at once mistake for them. Let us suppose the animal to have been killed, and the body opened while the heart was still pulsating. The right ventricle is charged with fluid blood; it may, however, contain coagula, formed, of course, during life. The left ventricle exhibits the characteristic spots of ecchymosis on its internal surface. On opening the abdominal cavity, it is seen that the portal vein and all its tributaries are full of dark fluid blood; the liver is congested, and the mucous membrane of the gall-bladder beset with minute ecchymoses. The mucous membrane of the stomach is also congested and beset with ecchymoses, but otherwise little altered; so that its condition contrasts markedly with that of the duodenum, which, just as in septicæmia, is the seat of intense congestion. The liquid contained in the duodenum consists of blood-stained mucus more or less mixed with bile. Numerous shreds, of various sizes, of shed epithelium float in it, easily distinguished by their yellowish tinge. On microscopical examination, the liquid is found to consist of young cells, coloured corpuscles in great numbers, shreds of epithelium, and abundant masses of bacteria. The mucous surface is of intense dark red. On microscopical examination, it is seen that the villi are the chief seat of the capillary extravasation. The capillaries of the villi are choked with coloured corpuscles closely packed against each other. They sometimes exhibit extravasations, but not as a rule. The mesenteric glands are intensely congested and soaked with sanguinolent liquid. In the large intestine, the changes are much less marked, though any fecal matter contained in the bowel is of a pitchy blackness. Finally, the blood does not coagulate; but there are no signs of solution of the coloured corpuscles; i. e., the liquid part of the blood is not ruby-coloured, as it is in real septicæmia—an important difference between this result and that of septicæmia, the meaning of which will be more apparent as we proceed.

If anyone here present happened to attend the meeting of the Pathological Society in 1872 (*Pathological Society's Transactions*, vol. xiii., p. 303), at which Dr. Klein and I exhibited to the Society the effects of the injection into the peritoneum or into the circulation of a very small quantity of peritoneal infective exudation-liquid, they will at once recognise the striking resemblance of the lesions of which I have now given a sketch with those then described. They resemble no less closely, as I have said, the infusion into the circulating blood of the virulent products of bacteria. In a word, the phenomena you have before you are those of intense septic toxicæmia; but (and it is to this fact that I would specially ask attention) they are produced, not by the introduction of any substance or contagium of extrinsic origin, but simply by the presence in the animal of the products of the disintegration I was going to say, but I must not anticipate—the products of the coagulation and exposure of its own blood. You have before you, in fact, an animal poisoned with its own blood.

To explain this action, I must ask your attention for a short time to some purely physiological considerations, which, however, if well founded, are of unquestionable pathological value and importance. Every bit of knowledge that helps the physician or surgeon to understand how it is that the hidden and intrinsic processes of disease go on, whether started by a morbid zyme from outside or not, is of value. Hence it is that an experiment like the one I have related to you, in which we are able to trace such a process, possesses a very great interest.

Every student is familiar with the inconvenient words fibrinogen and fibrinoplastin, by which Professor Schmidt of Dorpat has designated what he calls the fibrin factors, and is able to tell you that they are so designated because together they are supposed, according to what he pleases to call the newest views, to make fibrin. Your student would further tell you, if asked, that there is no fibrin in the circulating blood, that the fibrin of the clot is represented by the fibrinoplastin and fibrinogen of the liquor sanguinis; but that, somehow or other, although both of these factors are present, no coagulation occurs so long as the blood is contained in the vascular system; so that the immediate cause of the coagulation of the blood appears to be the withdrawal from it of the influence naturally exercised upon it by the living vessels.

The mode of the influence of the living artery or vein on its contents was, until lately, a mystery, to the solution of which the only clue was suggested by the observation that, in certain cases in which, notwithstanding that both "factors" were present, and that the liquid was no longer in the body, coagulation failed to take place or was unduly delayed, the desired result appeared to be brought about in some way or other with the aid of colourless blood-corpuscles. The only way in which this could be explained was by supposing that the corpuscles must contain some *tertium quid*, which, perhaps by a ferment-like action, determined, in the fibrin-producing constituents of the plasma,

\* *Ueber Trombose und Transfusion, Eiter und septische Infection und deren Beziehung zum Fibrinferment.* By Dr. Armin Köhler. Dorpat: 1877.

those molecular changes of which coagulation is the visible sign.\* Natural and simple as the suggestion seems, it was some time before it took more distinct form, and still longer before the agency of the colourless corpuscles in coagulation was established on the sure basis of experiment. Obviously, if the agent in coagulation be housed in the corpuscles, it must follow that, in order to its being free to act, at all events a certain number of them must be disintegrated. That such is really the case, we have now good reason for believing; but it has taken a long time and much laborious research to prove it. Let me now bring some of these reasons under your notice. I have to prove to you, first, that certain of the blood-corpuscles disintegrate from the moment that they leave the blood-stream; and, secondly, that if they are removed from the blood before this process commences, the concomitant process of coagulation is arrested.

The fact that the colourless corpuscles break up in the process of coagulation can be made matter of direct observation in any liquid in which they can be observed alone, that is, without the coloured blood-discs. The liquid which has been used for the purpose by Professor Alexander Schmidt is the separated liquor sanguinis or plasma of the horse.† It may be well that I should state how this is obtained. As every one knows, blood does not coagulate at the temperature of freezing. If you allow blood from a vein or artery to fall into a tall jar, in which it is rapidly cooled, and surround the jar by ice, the blood does not coagulate, and what is observed is that the corpuscles fall to the bottom, so that, in the course of an hour or two, you have the column of blood divided into two parts, of which the upper consists of liquor sanguinis alone. As the subsidence of the coloured blood-discs begins very soon after the blood is drawn, it is possible to collect colourless plasma from the top stratum almost immediately with the aid of a pipette. If this liquid be examined without delay, it is found to contain scarcely any blood-discs, but any number of colourless corpuscles; and, if the observation be continued, it is seen that a certain number of these leucocytes rapidly undergo disintegration. In this process of disintegration, the corpuscle breaks up to granules, which hold together for a time in the liquid, but eventually dissolve and disappear. That the disintegration is intimately connected with the process of coagulation, Professor Schmidt infers from the fact that the first formed filaments of fibrin can be plainly seen to originate from the heaps of granular *débris* which the corpuscles leave behind them.‡

I need scarcely say that the fact of the participation of the colourless corpuscles in the act of coagulation could not be accepted on the ground of microscopical observation alone, however careful or minute. In order to arrive at certainty on the subject, it is necessary to adopt such a mode of investigation as will bring the matter to the test of crucial experiment. It must be shown, not merely that when the corpuscles are withdrawn coagulation is arrested, but also that if, after such withdrawal and suspension of coagulation, they or their contents are restored to the plasma, the power of coagulation, before absent or diminished, is restored. The proof of the first of these statements has been rendered possible by the discovery that in plasma the leucocytes, though quite incapable, on account of their extreme lability, of being stopped by any filter at the ordinary temperature, acquire at the temperature of freezing such firmness and consistence that they are held back by the ordinary method of filtration. This being the case, it is a comparatively simple matter to obtain uncoagulated plasma as nearly as possible in the same condition as that in which it actually circulates, free from leucocytes, provided that the physiologist can work at a low temperature. The filtrate so obtained is absolutely transparent, and is, as nearly as may be, deprived of its power of coagulating; for when brought into an ordinary room, and subjected to a temperature of 60 or 70 deg. Fahr., it remains fluid for several hours.

The second fact, namely, the restoration of the power of coagulation by the subsequent addition to the liquid of the constituent of which it has been deprived, may also be demonstrated by the same method of

filtration. The colourless corpuscles are, as I have described, collected on a paper filter. In order to obtain them free from adherent plasma, they must be washed with ice-cold water. If, then, the filter be washed a second time with water rendered slightly alkaline by sodic carbonate, a solution passes through, which, when added to the decorpused plasma, again restores to it its original coagulability (Schmidt, *Die Lehre*, etc., p. 47).

It has further been established by A. Schmidt that all spontaneously coagulable fluids contain, in addition to what he calls the *substratum* for coagulation (viz., the fibrin factors), a body which is endowed with the properties of a ferment, by which is meant a substance which by contact excites chemical action without itself taking part in it. The function or endowment of the blood-ferment, as it is called, is to excite the molecular changes which result in coagulation, without itself taking any part in the formation of the resulting fibrin.

The blood-ferment is obtained from freshly coagulated blood by a method which resembles that by which, as I explained in my last lecture, I obtained my septic extract from putrid infusions; viz., by first subjecting the blood to the prolonged action of strong alcohol, and then extracting the precipitate with distilled water. The solution of the precipitate, which as so prepared has no toxic properties, exhibits a very remarkable power of exciting coagulation in coagulable liquids in which the process was previously delayed or restrained. If, for example, you receive bullock's blood into a vessel containing already a strong solution of Epsom salt, and allow the blood and solution to mix, you obtain a liquid which does not coagulate. If, after allowing the corpuscles to subside, you decant off the supernatant liquid, you have, of course, the plasma of the blood diluted with water holding magnesian sulphate in solution. If now you dilute this plasma sufficiently with water, it coagulates, because, as has long been known, the inhibitory power of the sulphate is neutralised by dilution. But, if, in adding the water, you stop short of this degree of dilution, you readily obtain a liquid which although, so to speak, on the point of coagulation, yet does not coagulate. Such a liquid is well adapted to exhibit the influence of any such body as we suppose the ferment to be. It is evident that it contains the substratum for coagulation; for it consists of liquor sanguinis and magnesian sulphate. Yet it does not coagulate until the required fillip is given to it by the addition of the ferment.

These facts admit of no explanation excepting the one given to them by general consent, namely, that, in addition to the substratum, the action of a ferment is necessary for coagulation, and, this having been admitted, the explanation at once suggests itself to the mind that it is in the leucocytes that the ferment is produced, and that this is one reason why they must be disintegrated, in order that coagulation should take place. The filtration experiment affords evidence that this explanation is correct; for it is found that, whereas plasma which contains its leucocytes is as rich in fibrin as the corresponding quantity of blood, plasma which has been deprived of them contains no ferment whatever. But we have already had the proof before us that this is not the only way in which they contribute to the formation of fibrin; for it has been shown that their absence not only prevents coagulation, but that the quantity of fibrin formed is proportionate to the number of corpuscles present. Hence they are not merely exciters of coagulation, but also furnish part of the material out of which fibrin is built up (*loc. cit.*, p. 51).

These considerations, relating to the participation of the leucocytes of the blood in the act of coagulation, readily afford us a way to understand the fact from which we started; viz., that blood which has been allowed to coagulate and then strained off from the clot and re-injected acts as a poison. Why does it do so? Obviously, because it contains disintegrated leucocytes, and thereby determines to a greater or less extent intravascular coagulation. Intravascular coagulation as a mode of rapid death is familiar to every one: a clot in the right ventricle, extending into the pulmonary artery; arrest of the circulation in the lungs; life extinguished by a process in which the phenomena of collapse are mixed with those of asphyxia. In some of the experiments on the reinjection of cruor, this effect was observed. The animal died collapsed and half asphyxiated, and, on opening the thorax immediately, it was found that the still beating heart contained a firm clot, which extended into the pulmonary artery. But, in those cases of longer duration in which the *post mortem* appearances corresponded so very closely with those of septicæmia, coagulation had indeed taken place, but the obstruction was not in the great vessels, but in the smallest arterioles. The contrast between the two kinds of coagulation was striking enough, the one inducing a systemic, the other a local effect; the one affecting the circulation close to the heart, the other near to the capillaries.

It will be remembered that the cruor was infused into the arterial

\* For the facts known in 1873, as to the influence of the colourless blood-corpuscles on coagulation, see the article on the Blood in the *Handbook for the Physiological Laboratory*, p. 173.

† Professor A. Schmidt has lately published a complete summary of his sixteen years' labours in the investigation of the coagulation of the blood, under the following title: *Die Lehre von der fermentativen Gerinnungs-Erscheinungen in der eissartigen thierischen Körperflüssigkeiten*. Dorpat: 1876.

‡ A similar process may be readily studied in the coagulation of blister-fluid, a drop of which may for this purpose be subjected to observation in a "moist chamber" on the "warm stage" of the microscope. Pericardial fluid, collected from the body of a horse or ox just slaughtered, can be used for the same purpose. Schmidt's microscopical observations relating to the coagulation of plasma are to be found in detail in a paper published in *Pflüger's Archiv* in 1875, p. 560, entitled "Ueber die Beziehung der Faserstoffgerinnung zu den körperlichen Elementen des Blutes". He concludes, from elaborate observations, that those of the colourless corpuscles which, on account of their containing coloured granules, may be regarded as transitional (*rother Körnerkugeln*), take a much more active part than the rest in the fibrin-producing disintegration.

blood-stream of a limb, and not into a vein; consequently it had to pass through the capillary system of the limb, and so become intimately mixed with the circulating blood, before it arrived at the heart. It is this fact which affords the key to the understanding of the result. The tendency to coagulation developed itself slowly, and affected the whole mass of the blood, its effect being to increase the viscosity, and not to produce clots. It was only in a few cases that visible plugs could be distinguished even in very small arteries; but the change in the properties of the blood showed itself in the production of stasis in those parts of the circulation in which stasis is most apt to be produced.

That the organs which send their blood to the portal vein were specially distinguished admits of a probable physiological explanation. In those parts, the difference between the arterial and venous pressures is less than anywhere else in the circulation, excepting in the lungs. But it may be asked, admitting that the circulation of crur produces embolism of capillary arteries, and that this is, on the whole, more likely to occur in the abdominal organs than elsewhere, how does this explain the localisation of the congestion of the mucous membrane in the duodenum and jejunum? For the answer to this question I need only refer to the facts relating to capillary embolism, of which I gave you an account here two years ago. We then saw that, whenever a terminal artery is obstructed (*i.e.*, an artery which is so exclusively distributed to a particular territory, that that territory receives no blood from any other source), the result is, that the capillaries become choked with blood; and that, by the exudation of the liquor sanguinis of the stagnant blood into the adjoining tissues, the relative number of corpuscles increases, so that in the end you have the capillaries completely plugged with coloured blood-discs, just as they are in the capillary stasis of inflammation. Hence the fact that, both in septic gastro-enteritis and in that produced by the injection of crur, the villi are the special seat of the injection may be readily understood; for it is obvious that the artery of a villus must necessarily be terminal. If it be choked, the capillaries of the villus will fill with blood as completely as those of the frog's tongue after obstruction or ligature of its principal arteries.

The value and significance of the experimental results we have been considering appears to me to lie in this: not that an analogy is established between septicæmia and the effects of corpuscular disintegration, but that they afford evidence that the particular symptoms produced are not specific, *i.e.*, are not dependent on any specific attraction between, *e.g.*, the mucous membrane of the duodenum and the septic virus, but on a physiological process for which all the conditions exist inside the organism. Thus, by simplifying the problem of the pathological nature of the conditions, we resolve the question of its action into a question of the disintegration of the colourless blood-corpuscles.

The analogy which we have now seen to exist between septic intoxication and the effect of the reinjection of crur, however remarkable it may be, must not mislead us to the conclusion that the two processes are identical; that is, to the inference that the whole effect of the septic poison is due to the premature disintegration of leucocytes. The symptoms which seem to me to stand apart from the rest in this respect are those which relate to the nervous system, and the pyrexia. As regards the former, their mode of production must for the present remain an open question. There are clinical facts relating to the subject, but they are not sufficiently definite to be dwelt on here. As regards the pyrexia, I think it very unlikely that it is produced by the disintegration of the leucocytes. It seems to me much more probable that the damage done by the septic poison has a wider range, and affects all the more unstable forms of protoplasm, that is, all the more active structures of the body; and that, in accordance with the view of fever which I submitted to you in my lectures here four years ago, the pyrexia which it produces is the expression of that general damage.

[To be continued.]

**STOMATOPLASTY.**—In a case of cicatricial contraction of the jaws, in which the mucous membrane of the cheek as far as the masseter, and the gums, were extensively destroyed, Dr. Gussenbauer replaced the mucous membrane by a pedunculated horizontal flap cut from the skin of the cheek, and turned so that the epidermic surface looked towards the interior of the mouth. At a second operation, the bridge of tissue connecting this flap with the exterior was divided, and fastened to the anterior part of the mouth. Finally, the defect in the exterior of the cheek was repaired by skin taken from the submaxillary region in the neck. The result of the operation was the restoration of the normal movements of the jaw. The case may be regarded as a typical one of the contractions which result from ulcerative stomatitis, noma, and injuries.—*Archiv für Klinische Chirurgie*, Band xxi; and *Centralblatt für die Med. Wiss.*, Dec. 29.

## A CASE OF RUPTURE OF THE INTERNAL AND MIDDLE COATS OF THE POPLITEAL ARTERY, AND COMPLETE RUPTURE OF THE POPLITEAL VEIN, FOR WHICH PRIMARY AMPUTATION OF THE THIGH WAS SUCCESSFULLY PERFORMED: WITH REMARKS.

By WALTER RIVINGTON, M.S.Lond., F.R.C.S.Eng.,  
Surgeon to the London Hospital.

THE comparative rarity of partial rupture of the popliteal artery will, I hope, impart sufficient interest to the following case to justify me in bringing it under the notice of the British Medical Association. The particulars of the case are these.

James Collins, aged 19, a muscular well built young man, of fair complexion, was sitting on the front seat of an omnibus; the retiring angles of his knees were in close correspondence with the projecting edge of the seat. A runaway horse and cart came rushing up and dashed into the omnibus. The cart was a railway cart with a high curved cover, and one corner of this cover struck against the patient's left knee and drove it backwards, so that the recess of the popliteal space must have come violently into contact with the edge of the seat. The patient was admitted into the London Hospital on Friday, May 8th, 1874, at 7.30 P.M., shortly after the accident. The left knee showed signs of severe contusion; but, on examination, Mr. Bowkett, the house-surgeon, did not detect any abnormal mobility. There was no evidence of a dislocation. There was not much effusion into the cavity of the joint, and the patient could bend it with only a slight amount of pain. The right knee was bruised. By 9 P.M., the swelling had greatly increased, and the patient complained of partial loss of sensation below the middle of the leg. On measurement, the circumference of the left limb, three inches above the upper border of the patella, was found to be seventeen inches, whilst that of the other side was only thirteen inches. At 11 A.M., the next morning, he was seen by myself. Great swelling existed above and below the left knee for some distance. The knee-joint was distended. The limb was perceptibly cooler than its fellow. The posterior tibial artery at the ankle yielded the faintest possible thrill, so faint, indeed, that most of those who examined the case could not perceive it. On auscultating the limb over the course of the popliteal artery, I detected a peculiar low clicking sound, much resembling the ticking of a watch under a pillow. The diagnosis formed was probable rupture of the popliteal artery and vein, either partial or complete. There was too much swelling to determine the existence of any accompanying fracture. It was decided to send for the friends, and to recommend amputation in the course of the afternoon. At 3.30 P.M., the patient was seen also by my colleague Mr. Hutchinson, who concurred in the diagnosis, and strongly advised the patient, who seemed at first unwilling to consent, to submit to the loss of his limb. By this time, the swelling had invaded the thigh and the leg farther, both upwards and downwards, and the foot was assuming a mottled aspect. The consent of the patient and his friends having been obtained, I amputated the thigh at the lower third, adopting a modification of Teale's method, which I have practised for some years. The anterior flap was rounded at the angles and cut rather shorter, whilst the posterior flap was cut rather longer, than the corresponding flaps in Teale's amputation. The greater portion of the anterior flap consisted of skin and fascia only. On completing the removal of the limb, we found that the areolar tissue underneath the skin of the posterior flap was infiltrated with dark blood for some distance, and, as it seemed possible that the part had been bruised and might slough, it was thought advisable, as a precautionary measure, to take away an inch more of the femur, so as to obviate all chance of subsequent protrusion. Accordingly, the periosteum was stripped up for an inch and the bone sawn off. Subsequently, however, not the slightest sloughing action took place, the blood previously effused undergoing absorption. Four or five ligatures were required; the flaps were brought together with wire sutures, simple dressing was applied, and the patient was sent to bed.

The progress of the case was scarcely interrupted by any unfavourable symptom. Both the temperature and pulse had a high range for a few days, as might have been expected, the former reaching 102 deg. and 103 deg., the latter 120; but, within a week, the temperature was at 99 deg. and the pulse 100. By the 15th, the flaps had united by first intention, except at the lowest part; and, by the 25th, the ecchymosed portions had regained the aspect of health. In the middle of June, the patient was going about on crutches, and, in another month, he was sent to the seaside, his stump being entirely healed. On his

return, he was ordered an artificial leg, the stump bearing pressure well.

Examination of the limb showed blood extensively infiltrated beneath the skin and in the planes of areolar tissue. The popliteal space was filled with dark blood, and dark blood flowed from the knee-joint through an opening in the posterior ligament, which had been slightly torn. The plantaris muscle was torn from its attachment to the femur. At the lower limit of the popliteal space, the popliteal vein was found completely severed, whilst the wall of the artery adjacent to the ruptured vein was evidently thinned. On laying open the artery, the inner and middle coats were seen to be separated from the external for half an inch and turned downwards towards the foot. The impulse of the current of blood against the loose flap had doubtless caused the clicking sound heard with the stethoscope. A further dissection of the parts was made by Mr. Clippingdale. He found that the internal popliteal and posterior tibial nerves were surrounded by dark coagulated blood, which had compressed them and reached nearly to the ankle-joint. On opening the knee-joint on the anterior aspect, he observed that the ligamentum mucosum had been torn through, and that the anterior crucial ligament was injured. A small quantity of dark blood still remained in the cavity of the joint. The external semilunar cartilage was partially displaced.

The external condyle was nearly separated from the rest of the femur by a deep fissure extending along its internal and anterior surfaces, whilst a small triangular piece of bone was loose and projected into the joint. A fissure, commencing behind the external tuberosity of the tibia, ran forwards across the articular surface down the front of the head to the upper end of the tubercle, where it bifurcated the inner branch, terminating on the inner side of the tubercle, whilst the outer branch ran down to the outer side of the tubercle, and, after dividing to enclose a triangular piece of bone, continued its course down the inner surface of the tibia for a distance of four inches. The fibula and the patella were uninjured. The fractures of the femur and tibia were effected by the corner of the railway-van, and at the same time as the rupture of the vessels; but they had no causative connection with the vascular lesions; they were simply a comparatively unimportant accompaniment of the ruptures.

REMARKS.—Rupture of the popliteal artery is, I believe, generally associated with displacement of the tibia at the knee-joint, and involves usually all the coats of the vessel. Such cases have hitherto of necessity required amputation; and the only question which arises in reference to the operation is, whether it is better to perform it at once as soon as the lesion is diagnosed, or to wait until gangrene has commenced. I think that the opinion of most surgeons would be strongly in favour of early amputation, whereby the patient would be saved from all risk of his blood becoming contaminated by the products of the decomposition of his tissues. More especially would this consideration weigh with a surgeon not yet converted to the antiseptic system, and attached to a metropolitan hospital where pyæmia is prevalent and mars the success of operations, however well conceived and executed they may be. In a primary amputation, the surgeon obtains healthy or nearly healthy flaps; in a secondary amputation, after gangrene has commenced and is spreading, he may have to cut through tissues infiltrated with inflammatory exudation.

In reference, however, to the actual results of cases, I am not in possession of sufficient data to determine the point. That secondary amputation may be attended with a very satisfactory result is shown by several reported cases. A case is related by Mr. Jackman in the fourth volume of the *St. Bartholomew's Hospital Reports*. The patient was a healthy farmer fifty-six years of age. He was superintending his men, who were removing some large stumps of old trees. The men had placed a chain round one tree, and, while the patient was standing with his back to them, the horses employed made a sudden plunge forward, which tightened the chain with a jerk and caused it to catch him just under the knee and throw him down with great force. Gangrene set in ten days after the accident, and amputation was performed above the knee four days later. The popliteal artery was torn across, but its ends were surrounded by a tumour about the size of a pigeon's egg, which had the appearance of a false aneurism. Both ends of the artery were closed. The state of the popliteal vein is not described.

Again, in the fifth volume of the *St. Bartholomew's Hospital Reports*, Mr. George Lowe has recorded two cases of complete dislocation of the tibia forwards at the knee-joint, with rupture of the popliteal vessels. The first patient was a fine healthy collier thirty-six years of age. Amputation was performed in the upper third of the thigh six days after the accident, when gangrene supervened. Both the popliteal artery and vein were found completely torn across. The patient made a good recovery. In the second case, amputation was performed in the

upper third of the thigh on the third day after the accident. The popliteal vessels were completely torn across. The patient was a comparatively feeble man thirty-two years of age, but he recovered well. The success of these three cases may be partly ascribed to the fact that the operations were performed in the country, and the success of two out of the three may be also ascribed to the healthy condition of the patients. It is worthy of note, however, that, in Mr. Lowe's cases, the accession of gangrene compelled amputation in the upper third of the thigh, whereas primary amputation could be performed, I should think, in most cases in the lower third. This difference tells considerably in favour of amputation before the occurrence of gangrene.

As a general rule, I think it may be stated that, in cases caused by contusion or dislocation, the popliteal artery can scarcely be torn across, either partially or completely, without corresponding injury to the popliteal vein. This complication must necessarily enhance the gravity of the case. Apart from additional interference with the circulation caused by interruption to the current of blood, the accompanying extravasation would be increased, and the probability of a circumscribed false aneurism forming and limiting the effusion would be considerably lessened.

In the case which I have related, the lower part of the thigh, the popliteal space, and the upper part of the leg were infiltrated with blood, and the knee-joint was distended, the foot was cold and becoming mottled, and yet the effused blood was derived wholly from the ruptured popliteal vein.

Rupture of the inner coats of a large artery is a lesion probably of unfrequent occurrence, and, although I have not had time to search in the various medical periodicals for cases, I believe that comparatively few have been placed on record. It is a lesion, however, which might readily be overlooked or mistaken for embolism. Where, for instance, the internal and middle coats of an artery are turned down and block up the artery, pulsation will be traceable as far as the obstruction, whilst the distal portion of the artery will be pulseless, at least as far as the first large branch, and the limb below, especially if the lower extremity be the seat of the lesion, will be colder than its fellow, just as in the case of an embolic block in the artery. Mr. Pick states that there is a specimen of partial rupture of the left axillary artery in the St. George's Hospital Museum, showing the two inner coats turned down, and involving the vessel in the third part of its course. It was taken from a man who died of an injury to the head. During life, pulsation could be traced to the lower part of the axilla. This is evidently the same case as that related by Mr. Holmes in his text-book of the *Principles and Practice of Surgery*. Mr. Holmes states that "the symptoms of the injury were so clearly marked that it was easy to diagnose both the nature and the precise seat of the lesion". The superficial situation of the artery at the injured spot rendered it obvious that the torn coats had been pushed into the tube of the vessel by the blood, so as to close it, and the condition of the artery was exactly verified by *post mortem* examination. A second specimen in St. George's Hospital Museum shows a laceration of the internal and middle coats of the femoral artery. A third case has been related by Mr. Pick in the seventeenth volume of the *Transactions* of the Pathological Society. The patient, twenty-five years of age, received a violent blow from a crowbar on the front of the right thigh, the effect of which seems to have been to cause a partial rupture of the popliteal artery. He experienced a sudden and intense pain at the back of the knee-joint, lasting some minutes and causing him to feel very faint. The pain passed off, and he resumed his work as a navigator, continuing at it for a week, in spite of pain and swelling of the limb. After walking several miles on the sixth day after the injury, he experienced pain so severe, and so much swelling, that he had to be conveyed home and confined to bed. Five weeks later, he was admitted into St. George's Hospital in a state of collapse and with enormous swelling of the left leg. Amputation of the thigh was performed. The patient rallied, but died of pyæmia on the nineteenth day after operation. The popliteal artery was found torn across, but not completely, a strip of the anterior wall still uniting the two ends. The vein was not injured, but its walls were thickened.

Partial rupture of a large artery may lay the foundation for an aneurism, either circumscribed or diffused. Mr. Pick has related, in the sixth volume of the *St. George's Hospital Reports*, a case of the kind. A policeman, thirty-one years of age, strained his left thigh. Five months afterwards, he was obliged to give up duty and go into the hospital, a pulsating swelling having appeared on the inner side of the thigh. Digital compression was tried, but proved inefficacious, and the swelling of the limb increased so much, that gangrene supervened and necessitated amputation at the hip-joint, from which the patient succumbed. The aneurismal sac was situated at the junction of the

femoral and popliteal arteries, and seemed to be largely formed of the external coat of the vessel. I have also placed on record a case of traumatic axillary aneurism, in which it was an open question whether a complete or partial rupture of a segment of the arterial circumference was the primary lesion. The patient was seventy years of age. Four days before admission, he had fallen out of a cart and displaced his left humerus at the shoulder-joint. Two days after the accident, the dislocation was reduced by a practitioner by extension with the foot in the axilla. On admission, there was considerable, but not excessive, swelling of the shoulder-joint, without pulsation in the swelling. The pulse beat naturally at the wrist. A small hard lump, about the size of a pigeon's egg, could be felt at the base of the axilla, over the site of the axillary vein, and not receiving impulse from the axillary artery. Under these circumstances, more fully detailed elsewhere, I diagnosed an effusion of blood into the axilla and shoulder-joint, stating my belief that the blood came, not from a ruptured axillary artery, but either from smaller vessels or from the vein. Strict rest, with bandages only, was enjoined to promote absorption. A month later, when the patient was not under my charge, aneurismal symptoms appeared, pulsation and *bruit* being both perceptible, and the pulse at the wrist became feeble. Various suggestions as to treatment were made, the most prominent being ligature of the subclavian artery; but the patient declined operative interference. Ultimately, ulceration of the skin took place, hæmorrhage occurred, the axilla was laid open, and the injured vessel was secured at the seat of lesion. A transverse aperture was found in the third part of the course of the axillary artery, occupying about a third of the circumference of the artery. In view of the uncertainty as to the source of the effusion of blood in this case, and the advanced age of the patient, which rendered any operative interference at any stage of his case wellnigh hopeless, there can be no doubt as to the propriety of the treatment recommended in the first instance by myself. I am pleased to have the opportunity of quoting a published opinion of my colleague Mr. Maunder in reference to this subject. In his Lettsomian Lectures (*vide Lancet*, February 27th, 1875, page 295, Case 24), Mr. Maunder speaks strongly against the application of a ligature to the subclavian artery, and states that either of the two other means of treatment at our disposal, amputation at the shoulder-joint and laying open the axilla, would in all probability have terminated fatally. This opinion effectually disposes of the suggestions made at the time that ligature of the subclavian artery ought to have been performed, and that it would have been better to operate at an early period in the history of the case.

A point of considerable interest arising out of this case is the possibility of locating the seat of injury in some of the cases of ruptured axillary artery. It is evident that, if the third part of the artery be involved, and if this can be rendered probable, the severe procedure of laying open the whole anterior wall of the axilla might be avoided. A careful exposure of the third part of the artery would then be sufficient, combined with a simultaneous removal of the clots in the axilla. The introduction of the finger would probably enable the surgeon to trace the vessel and find out where pulsation ceased or became less marked even in a case which he had not previously seen. If, however, the case had come under his observation early, and there existed, as in my own case, a small hard circumscribed lump over the third part of the course of the vessel, the diagnosis would be rendered more probable. At all events, a more prolonged search for the seat of injury should be made whenever such a course is practicable, without danger of serious hæmorrhage continuing during the exploration.

Next, I would strongly recommend the application of the stethoscope over the site of an artery which there is any reason to think is ruptured either partially or completely. There is good reason to believe that, by means of auscultation, partial and complete ruptures may be diagnosed in some cases shortly after the injury, and when pulsation cannot be perceived. Mr. Holmes states that he has never seen any case where pulsation was present in the extravasated blood in connection with a complete subcutaneous laceration of an artery; but he says that, in some cases, a *bruit* can be heard (*Surgery: its Principles and Practice*, page 78).

Lastly, in these days of antiseptic surgery, when knee-joints can be laid open and fingered with impunity, when the surgeon is freed from all anxiety as to the results of operations, when exposed blood-clots cease to break down and decompose, but become organised in the open wound under the charm of carbolic acid and the antiseptic dressing, it may fairly be asked whether, in such cases as that which I have related, amputation should not be set aside until the wounded vessels have been sought for and tied in the popliteal space. Some of the extravasated blood could be removed by the operator and the rest be allowed to become either organised or absorbed; and, if the knee-joint

had been opened by the accident, the triumph of antiseptic surgery would be all the greater. The only possible question would be, whether the circulation in the member could be carried on sufficiently to prevent the occurrence of gangrene. If this question should be capable of receiving an affirmative reply, no excuse would be left for the mutilation hitherto regarded by septic surgery as indispensable to save the life of the patient.

## THE BEARING OF EXPERIMENTAL EVIDENCE UPON THE GERM-THEORY OF DISEASE.

By H. CHARLTON BASTIAN, M.D., F.R.S., F.L.S.,

Professor of Pathological Anatomy in University College, London, and Physician to University College Hospital.

THOUGH it may be conceded that with our present state of knowledge an affirmative decision in regard to the absolute proof of the present occurrence of archæbiosis may be still withheld, there is, I think, no similar warrant for suspense of judgment in regard to the germ-theory of disease, or, as it is also called, the doctrine of *contagium vivum*. Existing evidence seems to me abundantly sufficient for the rejection of this doctrine as untrue.\*

My urine and potash experiments will go far to illustrate this difference in the weight of the evidence in regard to the two questions.

A "sterilised" fluid—that is, one which left to itself would always remain pure—may be caused to ferment by the addition of a certain proportion of liquor potassæ devoid of all living things, especially if the influence of the potash be favoured by certain accessory physical conditions. This fact is admitted by M. Pasteur himself. During the fermentation thus initiated, a matter (ferment) appears and increases, which is capable of spreading a similar process far and wide in suitable media.

But, on the strength of the analogy upon which the germ-theorists rely, we may find in such an experiment a warrant for the belief that in a healthy person, free from the contagium of typhoid fever or any other of its class, certain kinds of ingesta (solids or fluids), wholly free from all specific poison, may, with or without the favouring influence of other altered conditions, give rise to an independent zymotic process. And during the process thus initiated, a matter (contagium) appears and increases in certain of the fluids or tissues of the body, which is capable of spreading a similar disease far and wide amongst receptive members of the community.

Can the germless liquor potassæ, *plus* the favouring conditions (the principal of which is a certain high temperature), be regarded as the "cause" of the fermentation? The answer does not admit of doubt; the effect in question would not have taken place without their influence. The old logical formula in regard to the word, *cessante causâ cessat et effectus*, completely justifies this point of view, and so also does the definition of Sir John Herschel. A "cause," said this philosopher, is "an assemblage of phenomena which occurring, some other phenomenon invariably commences or has its origin".

But there is a point of view which must not be lost sight of. It is of considerable importance, and has of late been dwelt upon by G. H. Lewes with his usual force and clearness. He says: "The fact, that it is a convenience to select some one element out of the group, either for its conspicuousness, its novelty, or its interest, and that we call it the cause of the change, throwing all the other elements into the background of conditions, must not make us overlook the fact that this cause—this selected condition—is only effective in coalescence with the others. Every condition is causal; the effect is but the sum of the conditions."

This brings us to the only point of doubt which can possibly exist in regard to the interpretation of my experiment. It is, whether our

\* Since this paper was read, the doctrine has again been proclaimed—and never with more force and ability—by Dr. William Roberts (*BRITISH MEDICAL JOURNAL*, August 11th, 1877). Its essential points may be stated in the words of its latest exponent. He says: "I have already directed your attention to the analogy between the action of an organised ferment and a contagious fever. The analogy is probably real, in so far, at least, that it leads us to the inference that a contagium, like a ferment, is something that is alive. . . . If, then, the doctrine of a *contagium vivum* be true, we are almost forced to the conclusion that contagium consists (at least in the immense majority of cases) of an independent organism or parasite; and it is in this sense alone that I shall consider the doctrine. . . . It is more than probable, looking to the general analogy between them, that all infective diseases conform in some fashion to one fundamental type. If septic bacteria are the cause of septicæmia, if the spirilla are the cause of relapsing fever, if the *Bacillus anthracis* be the cause of splenic fever, the inference is almost irresistible that other analogous organisms are the cause of other infective inflammations and other specific fevers."—Sept. 1877.

† *Problems of Life and Mind*, vol. ii, p. 390.

most prominent causal element, the liquor potassæ, exercises its influence (a) partly upon the fluid and partly upon certain otherwise dead or impotent germs still lurking within the vessel, or (b) simply upon the mere chemical constituents of the fluid medium, but in such a way as actually to engender minute particles of living matter which thereafter appear as ferment-organisms.

If a practically dead germ can by any treatment be revived, it may take its place as one of the causal conditions leading to fermentation; hence it is that a certain reserve may still be maintained as regards the absolute proof of the possibility of a germless origin of common fermentations, and the almost simultaneous occurrence of a new birth of living units (Archebiosis).

But all similar grounds for reserve are absent—are non-existent, in fact—in regard to the bearing of this experiment upon the possibility of an occasional independent origin for zymotic disease, whether or not such disease is characterised by the appearance within the body of any distinctive living organisms.\*

This I will now endeavour to demonstrate.

It is the process of fermentation which is supposed to be in part analogous to the zymotic disease. It is true that a contagious something becomes engendered during fermentation and during zymosis, by means of which the process or the disease may be spread abroad. But there are important differences in regard to the possible independent origin of the two processes which have hitherto been only too much neglected. The treatment of this subject has often been much too superficial. In order to produce a kind of pictorial effect which may easily captivate the imagination, difficulties are often ignored, and many new, modifying, or antagonistic points of view have even of late been treated as though they were non-existent.

A few words will suffice to make plain some of the differences between the respective conditions which would be operative in the germless origin of fermentation on the one hand, and in the *de novo* origin of a contagious disease on the other. And in so doing I shall be able, I think, at the same time, to show how much simpler it would be to bring about an independent zymosis than an independent fermentation—that is, if we are to rely on the analogy upon which the germ-theorists base their arguments.

During the great majority of fermentations, living organisms make their appearance and rapidly multiply. These living organisms have been proved to be common producers of chemical principles, some of which are soluble ferments, others (like pyrogen) are poisons which may be almost as deadly as that of a serpent, whilst others still are inert and appear as mere pigment granules. It is proved that some of these chemical principles act as true ferments.† It is thought, and it is probable, that the organisms themselves—altogether apart from their media and what else they may contain—may be capable of doing the same. Still this has not yet been definitely proved; so that the action of soluble chemical ferments is at present almost better substantiated than that of the living organisms by which they may have been formed. By means of boiling alcohol and other agents, these bodies can be isolated and freed from living impurity. It is, however, much more difficult entirely to separate minute living organisms from their media,‡ and consequently more difficult to be perfectly certain in regard to their potencies. It is, however, on account of the derivation of the chemical ferments from the living units, and because of the presence of these latter bodies in all fermenting mixtures, that their own agency is still regarded by many as essential to the initiation of ordinary fermentations. But, as I have already indicated, we much need further information as to the precise mode in which fermentation is initiated and carried on by soluble ferments like that which M. Musculus discovered in and separated from urine. If they (all or any of them) are capable of setting up fermentations in germless fluids, in the course of which organisms appear, such phenomena would most effectually disprove an exclusive germ-theory.

Turning now to the process of zymosis, we find the available generative conditions altogether different. Here we have to do not with fluids only, but with tissues and organs composed of living elements characterised by all kinds and degrees of activity. Some of them produce the various soluble ferments of the body, some may produce poisons, and others habitually lead to the formation of pigment-granules—vital acts severally similar in kind to those which the common fer-

ment-organisms are known to manifest. Tissue-elements without number having such and multitudes of other properties are therefore ever present, capable, under certain influences, of being more or less easily diverted into unhealthy modes of action, so that many of them may become true living ferments in the modern sense of that term,\* and, therefore, possible producers of chemical ferments (contagia) capable of initiating some or the whole of the series of changes by which they were themselves produced, in other suitable sites.

The essential difference between the two problems thus becomes plain. The only point which my experiment leaves in the least doubtful in regard to the causal conditions initiating fermentation is, whether any latent, powerless, and, as it were, dead organised ferment may still, in spite of the usual evidence to the contrary, lurk in the seemingly "sterilised" fluid. This, however, is the very point about which there is no shadow of doubt in regard to zymosis. Possible ferments without number are, by necessity, present in the form of tissue-elements. So that if we are to be guided by the analogy upon which all germ-theorists so strongly rely, the independent generation of a zymotic process should, for the reason above specified, be incomparably more easy to be brought about than fermentation in a germless fluid. In regard to the independent origin of a zymosis, the all-important point is, not whether latent ferments exist, but whether any causes, or sets of unhygienic conditions, can rouse or modify, in certain special modes, the activity of any of these myriads of potential ferments of which the human organism is so largely composed. And if, as some germ-theorists would have us believe, impotent germs of common ferment-organisms, incapable of exclusion, are also widely disseminated throughout the body, these, if they are such unavoidable elements, could (in regard to the etiology of disease) only be looked upon as components of the body, ranking side by side with the tissue-elements themselves.

Thus such organised ferments or germs as are possibly absent from the "sterilised" experimental fluids are confessedly present by myriads in persons who may be sickening under the influence of various unhygienic conditions or non-specific states of the system; and the only point which is regarded as doubtful in connection with the *de novo* origin of a zymosis, is what analogy might lead us to affirm as completely proved by my experiments, viz., that certain conditions, or states of system, may be capable of rousing some of such ferments into a specific kind of activity, wholly apart from the influence of any specific contagia coming from without.†

Even if independent ferment-organisms of common or special kinds do make their appearance during any process of zymosis originated in the manner above suggested, they would, from the point of view of the etiology of disease, be just as much consequences of the morbid influences, as proliferation of tissue-elements is a consequence of the direct application of acetic acid or any other irritant.

But here, in order to make this point of view more plain, a short digression is necessary.

The intracellular fermentation in vegetal tissues supplies us with a kind of link between the ordinary processes of fermentation and the zymotic processes of animals. MM. Lechartier and Bellamy, as well as Pasteur and others, have now clearly shown that in vegetal tissues placed under certain abnormal or unhealthy conditions, fermentative

\* How legitimate this statement is may be seen from what M. Pasteur himself says. These are his most mature views: "I have been gradually led to look upon fermentation as a necessary consequence of the manifestation of life, when that life takes place without the direct combustion due to free oxygen. . . . We may partially see, as a consequence of this theory, that every being, every organ, every cell which lives or continues its life without making use of atmospheric air, or which uses it in a manner insufficient for the whole of the phenomena of its own nutrition, must possess the characteristics of a ferment with regard to the substance which is the source of its total or complementary heat."—*Compt. Rend.*, 1872, t. lxxv. p. 784.

† A very interesting address by Dr. B. W. Richardson, F.R.S., has been lately published (*Nature*, October 4th, 1877), entitled "A Theory as to the Natural or Glandular Origin of the Contagious Diseases". In it the author advances many strong arguments against the germ-theory; he also propounds some interesting speculations as to the mode of origin and action of the chemical principles, or poisons, which constitute, as he believes, the "contagia" of the communicable diseases. Some such views make a very fitting supplement to the doctrines which I have been here attempting to establish in regard to these diseases; only we must, as Dr. Richardson observes, seek gradually to put well proven facts in the places now occupied by mere speculations. In regard to the practical aspects of the two opposite doctrines, Dr. Richardson makes some very pertinent observations. "If the *contagium vivum* view be true," he says: "if the air around us is charged with invisible germs, which come from whence we know not, which have unlimited power to fertilise, which need never cease to fertilise and multiply, what hope is there for the skill of man to overcome these hidden foes? Why on some occasion may not a plague spread over the whole world, and destroy its life universally? Whilst, on the other hand, if the opposition notion be true, we have complete mastery over the diffusion of the poisons of all the communicable diseases. We have but to keep steadily in view that the producing and the reproducing power is in the affected body; and we can, even with our present knowledge, all but completely limit the action to the propagating power of that body—its power, I mean, of secretion and diffusion of secretion."—October 6th, 1877.

\* The rule is, that organisms are present in fermentations, whilst they are, so far as we know, quite exceptional in zymotic diseases.

† Pasteur, *Compt. Rend.*, July 3rd, 1876, p. 4.

‡ The more efficient means of filtering organisms from their media, which we now possess, by means of porous earthenware, ought to be useful in this direction. Such organisms and their germs might be subsequently washed with several distilled waters, just as a chemist would wash a delicate precipitate. It would be strange indeed if this very mild usage interfered with the properties of organisms which at other times are credited with such remarkable powers of endurance.

2. Facts of this second order have been thoroughly established by the important researches of Professor Burdon Sanderson. He says: "If a few drops of previously boiled and cooled dilute solution of ammonia are injected underneath the skin of a guinea-pig, a diffuse inflammation is produced, the exudation liquid of which is found after twenty-four hours to be charged with bacteria." "Other chemical agents", he adds, "will lead to the same results, and always under conditions which preclude the possibility of the introduction of any infecting matter from without."

Elsewhere,† the same investigator refers to experiments which were made about the same time in order to throw light upon the cause of the appearance of bacteria in certain peritoneal exudations, and to ascertain whether or not their presence was to be considered as "a mere result of the intensity of the peritonitis". He says: "To determine this, experiments were made during the following month (May 1871), which consisted in inducing intense peritonitis by the injection, not of exudation liquids, but of chemical irritants, particularly dilute ammonia and concentrated solution of iodine in hydriodic acid. As regards the ammonia, precautions were taken to guard against contamination by boiling and cooling the liquids, as well as the implements to be used, immediately before injection. In the case of the iodine solution, this was, of course, unnecessary. In every instance, it was found that the exudation liquids, collected from twenty-four to forty-eight hours after injection, were charged with bacteria, whence it appeared probable that the existence of these organisms was dependent, not on the nature of the exciting liquid by which the inflammation was induced, but on the intensity of the inflammation itself."

From the various evidence, more or less fully referred to in the present section, it seems to me legitimate to conclude:

First, that, if we are to be guided by the analogy now dwelt upon as existing between fermentation and zymosis, it would be perfectly certain that the latter process can originate *de novo*—that is, under the influence of certain general or special conditions, and where specific contagia of any kind are at first absent, though they subsequently appear as results or concomitant products. So that an exclusive theory of "contagion", as the only present cause of communicable diseases, is not supported by experimental evidence.

Secondly, that some contagia are mere not-living chemical principles, though others may be living units.

Thirdly, that, even in the latter case, if the primary contagious action be really due to the living units and not to the media in which they are found, such primary action is probably dependent rather upon the chemical changes or "contact actions" which they are capable of setting up than upon their mere growth and vegetative multiplication.

Fourthly, that, where we have to do with a true living contagium (whether pus-corpuscle or ferment-organism), the primary changes which it incites are probably of a nature to engender (either in the fluids or from the tissue elements of the part) bodies similar to itself, so that the infected part speedily swarms therewith. When pus from a certain focus of inflammation comes into contact with a healthy conjunctiva, and therein excites a contagious form of inflammation, no one adopts the absurd notion that all the pus-corpuses in this second inflammatory focus are the lineal descendants of those which acted as the contagium; and the mode of action may be altogether similar when matter containing bacilli, by coming into contact with a wounded surface, gives rise to splenic fever and the appearance of such organisms all through the body. The old notion about the excessive self-multiplication of the original contagium is probably altogether erroneous.

Thus, all the distinctive positions of those who advocate a belief in the so-called "germ-theory of disease", or rely upon the exclusive doctrine of a "contagium vivum", seem to be absolutely broken down and refuted. We may give that attention to the appearance and development of independent organisms in association with morbid processes which the importance of their presence demands, but we must regard them as concomitant products, and not at all, or except to an extremely limited extent, as causes of those local and general diseases with which they are inseparably linked.

dantly distributed, similar to these which Messrs. Cresswell and Lloyd have found. Some were bacilli, and some were more like what I am now designating as vibrios. They were not so abundant as to be always visible without careful examination, and a certain number lay in the diseased spleen, but there were a multitude of small angular crystals, which an inexperienced observer might mistake for motionless organisms. In the lower healthy portion of the spleen no organisms were found.

## ON REDUPLICATION OF THE FIRST SOUND OF THE HEART.

By PHILIP BINDLEY, M.B.Lond.,

Assistant-Physician to the General Hospital, Birmingham.

IN commenting on reduplication and accentuation of the sounds of the heart, it is necessary, in order that all ambiguity may be avoided, to state at the onset what is considered to be the mechanism of the sounds. Here, however, it is not proposed to enter upon the controversy, but merely to specify that in the following observations the first sound is considered to be caused by tension of the auriculo-ventricular valves, and the second by tension of the semilunar valves.

The fact that a doubling of the first sound of the heart sometimes occurred was known to the older authors; but, in his Lumleian lectures, the late Dr. Sibson propounded a theory, that this reduplication is due to an asynchronous action of the ventricles; and Dr. George Johnson, in the Lumleian lectures for the year 1877, propounds another theory, that it is due to an audible contraction of a dilated and hypertrophied auricle. The condition in which this phenomenon is most frequently observed to exist is an abnormal degree of arterial tension, which is a constant accompaniment of Bright's disease. Briefly, Dr. Sibson's theory is this. In consequence of the greater tension of the arteries, the left ventricle, meeting with an increased resistance, acts more tardily than the right; hence, a doubling of the first sound. Generally, there is no doubling of the second sound; and this is a difficulty which at first sight appears to stand in the way of accepting the theory of asynchronism. Dr. Sibson met this difficulty by the following explanation. The greater tension, both relative and absolute, of the aorta, causes it to recoil more rapidly than the pulmonary artery and make up in speed what it has lost in time, the two arteries thus delivering their backstroke at the same instant.

Dr. Johnson considers that this explanation raises a more formidable difficulty; for, if "the greater tension of the aorta, in the cases of renal disease under consideration, enable it to overtake the earlier but less rapidly and forcibly contracting pulmonary artery, it seems obvious that, in the normal condition, when the aorta and the pulmonary artery commence their elastic contractions at the same instant, the much greater tension of the aorta, with its thicker and stronger walls, should react upon and close its valves before those of the more feebly contracting pulmonary artery are closed, and the result would be reduplication of the second sound as a constant and normal condition".

And again, Dr. Johnson says, in reference to cases of emphysema: "In these cases, the increased tension of the pulmonary artery consequent on the obstruction in the lungs can never equal the normal tension of the aorta. However great may be the hypertrophy of the right ventricle in cases of emphysema, the thickness of its wall is never equal to that of the left ventricle. If, then, in accordance with Dr. Sibson's theory of asynchronous ventricular contraction, the right ventricle, in consequence of increased tension in the pulmonary artery, complete its contraction later than the left, and thus cause the doubling of the first sound, the closing of the pulmonary valves must inevitably be effected later than that of the aortic, and the second sound must also be doubled. The reverse, however, is the case. The second sound is single in these cases of emphysema, while the first is distinctly reduplicated."

It is difficult to see the point of Dr. Johnson's criticism. In normal conditions, the pulmonary artery is quite as capable of receiving and reacting against the stroke of the right ventricle as the aorta is against the stroke of the left ventricle. To deny this, amounts to the same thing as saying that a certain degree of elasticity reacting against a given pressure is not exactly equivalent to a greater degree of elasticity reacting against a proportionately greater pressure. It may require a cable to lift a ton, but a thread will lift a pound. The resilience of the pulmonary artery is the exact equivalent in force to the resistance offered by the smaller vessels in the lung, and the thickness and strength of its coats are adequate to the tension to which they are subjected. If, at any time, this natural relation between power and resistance become altered for any cause, then the rapidity of recoil must necessarily be altered too. For instance, if the *vis à fronte* in the lungs be heightened or diminished, then the pulmonary artery will be correspondingly more tense or less tense, and react more speedily or less speedily, in the same manner as a spring tightly or slightly wound.

In mitral regurgitation, the blood returning from the lungs meets with an already full auricle, and pulmonary congestion results; the arteries do not discharge their blood with the usual facility, the pulmonary artery becomes distended and its tension at the same time in-

My attention was first called to them by Dr. Wade, and I am indebted to him for kindly allowing me to make reference to them here. A number of these cases were treated by Dr. Wade with weak alkaline solutions, as recommended by him in a recent number of the *Practitioner* (April 1877). The rapid improvement was very remarkable; but what I wish especially to refer to is the changes that took place in the circulatory system. The arterial tension soon diminished, and the reduplication gradually became less, until at last a stage was reached when it required some care to determine positively whether or not it was present at all. If the auricular contraction were the cause of this reduplicate sound in these cases, then it is necessary to suppose that, as the arterial tension passed off, the auricular systole was followed more and more quickly by that of the ventricle, till at length the time between the two systoles was reduced to nothing. But it is known that the one occurs about one-tenth of a second before the other in a heart beating sixty to the minute.

### CHEIRO-POMPHOLYX.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital, etc.

I HAD certainly hoped that all personal discussion between Dr. Tilbury Fox and myself as to "priority of observation" was long ago at an end. The facts were very fully put before the profession, and might well have been left to its decision. After the expiration of a year, however, the subject is reopened, and Mr. Tweedy has been induced to forward to the JOURNAL his record of a conversation with me which occurred as long ago as 1873. The publication of statements made in conversation is always of questionable propriety, and especially so when the interval is long. Memories are treacherous; and, where the parties concerned differ, it is impossible to decide. Now, although I do not dispute Mr. Tweedy's verbal accuracy, my memory as regards the general bearing of what passed on that occasion is different from his. His letter appears to me to imply (although in this I may be mistaken) that at the date referred to I asked him about the disease in question, it being at the time comparatively new to me. The conversation took place at my desk at the Moorfields Ophthalmic Hospital. I cannot be quite certain, but I believe that a case which was present suggested it. I described to Mr. Tweedy, as I had done a hundred times before to others, the peculiar disease which I then named "relapsing bullous eruption on the hands", and for which I then proposed that of cheiro-pompholyx. I was just as familiar with the features of that disease then as I am now; and, if I asked Mr. Tweedy, as he says I did, if he knew it, the question was not put in the search of information respecting it. Mr. Tweedy suggested to me that it was the same disease which Dr. Tilbury Fox called dysidrosis; and, after a remark or two as to the etymology of that word, I said that my malady had nothing whatever to do with sweating. Mr. Tweedy said nothing in defence of the dysidrosis theory. On the contrary, I quite understood that he did not support it; and there, so far as Mr. Tweedy and myself were concerned, the matter ended. I subsequently, as I have previously stated, received a courteous letter from Dr. Fox, inviting me to read his writings on dysidrosis. This, I regret to say, I never did.

Let me just add that it was the theory involved in the name dysidrosis which prevented me from ever realising the possibility that Dr. Fox had really described the same malady which had so much interested me. I felt so confident that my "relapsing bullous eruption on the hands" had nothing to do with impeded sweating, and that so definite and wide a term as "dysidrosis" must comprise much more than this curiously local malady, that I never gave the subject the attention which it ought to have claimed. May I suggest, further, that this constitutes a strong objection to the use of the term? I have no desire to pre-judge the question as to the anatomical site of the fluid in the sago-grain. It is possible, after all, that that fluid is sweat. We must wait for evidence. But meanwhile it is not, I submit, convenient to designate the disease as if its nature were established, nor to use a term which is etymologically applicable to much more in exclusive reference to one local and clinically very peculiar form. If future investigation should show that in cheiro-pompholyx the initial lesion is, as Dr. Fox and Mr. Tweedy think, a distended sudoriparous duct, still it will remain only one variety of dysidrosis. Names based upon a single physiological hypothesis are seldom appropriate to maladies which present us with a complex group of clinical peculiarities. When it is wished to recognise such groups of symptoms by a name, it seems to me much better to use one which is comparatively meaningless. As such, I still prefer the one which I proposed; and, as a further reason for continuing to

use it, may state that I still agree with Dr. Robinson of New York, Dr. Thin, and others, in believing that cheiro-pompholyx has nothing to do with dysidrosis.

It appears to me that, since the publication of Dr. Robinson's able paper, the proof of the matter is not difficult to come at. If Dr. Fox can demonstrate that there is a bullous eruption on the hands, the fluid of which, in the earliest stage, is acid and does not coagulate, many of us will believe that *dysidrosis extremitatum* is a reality.

## OBSTETRIC MEMORANDA.

### CONGENITAL UMBILICAL HERNIA.

I ATTENDED Mrs. McK., aged 44, in her eleventh confinement, on November 9th, 1875, when she was delivered of a small female child. It appeared to be healthy and otherwise well formed, with the exception of a small conical hernial projection into the umbilical cord. The convolutions of the bowel could be distinctly seen through the cord. The child died on the sixth day, from what I considered to be peritonitis. Whilst Mrs. McK. was sitting before the fire shortly prior to the birth of the child, the waters suddenly escaped, and she remarked to me on my arrival as to their great quantity.

This deformity is one which we should expect to be of comparative frequency, when we consider the development of the foetus from an embryological point of view. I think this will be borne out by notices of cases in the various authorities on deformities. Vrolik has an illustration of this deformity in his beautiful Atlas (*Tabula ad illustrandam Embryogenesisin*), and A. Förster, in his short but complete work (*Die Missbildungen der Menschen*), has two diagrams. J. F. Meckel (*Handbuch der pathologischen Anatomie*) describes a number of cases, in some of which the liver, stomach, and part of the intestines were contained in the hernial sac.

According to M. Vrolik (*Cyclopaedia of Anatomy*), this deformity is caused by an arrest of development at that stage in which a part of the viscera is contained in the sheath of the umbilical cord. He also states that the viscera lying in it are always in an imperfect condition. He mentions that there were only four cases in which the life of the malformed child lasted for any time after birth, in the case of Van der Voort for eight, and in that of Ribko for twelve months.

According to some authorities, excess of the liquor amnii is a cause of deformity; but whether it be or not, it is impossible to judge from one case. Its *modus operandi* may be conceived from its pressing on the abdominal walls, and thereby protruding the viscera. It will likewise be seen that the mother was a multipara, and, according to J. G. St. Hilaire (*Histoire des Anomalies*, tome iii), deformities occur more frequently in them than in primiparae; and, in my own short experience, 90 per cent. have been in multiparae, the other 10 per cent. occurring in the somewhat exceptional case of an unmarried primipara.

WILLIAM SNEDDON, M.D., Beith, N.B.

### SUDDEN DEATH THREE WEEKS AFTER DELIVERY FROM THROMBOSIS OF PELVIC VEINS, WITH EMBOLISM AND OBSTRUCTION OF PULMONARY VESSELS.

S. W., AGED 27, a fair somewhat delicate woman, living about two miles from my residence, was delivered of her third child on November 24th. The labour was natural and the placenta readily detached. She progressed satisfactorily, and was seen up to the tenth day. On December 19th, between 9 and 10 A.M., I was summoned in haste to see her; but on arrival found her dead. On inquiry, it appeared that, on December 16th, she had complained of pains, supposed to be rheumatic, in the joints, especially the left hip and in the legs; she was said to have been feverish and to have sweated a good deal. She then had cough and shortness of breath. On the morning of her death, on coming downstairs, she was seized with sudden and intense dyspnoea, complained of pain in the region of the heart, and shortly expired.

I made a *post mortem* examination on the 21st, and found both lungs, especially the upper lobes, much congested, with here and there extravasations of dark coagulated blood in their substance. The left lung was bound down by old adhesions. The branches of the pulmonary artery were filled with reddish-brown friable coagulum. In the right ventricle was a cylindrical partly decolourised firm yet friable clot. The veins of the broad ligament, on the left side, and the trunks of the internal and common iliac veins of the same side, were filled with a coagulum of similar character. In the trunk of the right ovarian vein, just before its junction with the inferior vena cava, was a coagulum of the same character as those before mentioned. The vena

cava itself was empty. There were no signs of inflammatory action about the pelvis. The walls of the uterus were flabby, and its cavity was lined by a red shreddy flocculent membrane.

HERBERT J. LLOTT, M.B., M.R.C.S.E., Bromley, Kent.

### SPONTANEOUS EXPULSION.

ON November 30th, 1877, I was called to Mrs. W., aged 23, primipara. On examination, the os was fully dilated, the membranes ruptured, the shoulder presenting. The child was dead, the pelvis roomy, and the shoulder well down. I resolved to leave the case to Nature. The forearm soon appeared at the vulva, the head rested on the pubes, the dorsum of the child over the sacrum. The shoulder steadily descended. The left side of the thorax sank lower and lower in the hollow of the sacrum, and kept pace with the descent of the head, which was doubled on the thorax, so that the right cheek lay over the right subclavicular region. The pressure thus caused drove in the thorax and flattened the cheek. Yielding to the pains, the occiput anteriorly, and the lower part of the left side of the thorax posteriorly, were extruded coincidentally at the vulva. Two or three more pains sufficed to complete the delivery of the trunk. The child weighed only five pounds. Labour had commenced at 4 A.M. I first saw the patient at 12.30 P.M., and the delivery was terminated at 3 P.M. The child-bed was normal. The perinaeum was uninjured. This seems to be an example of what is known as *expulsio corpore conduplicato*.

ALEX. FORD, Harrogate.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CONSULTATIONS.

December 27th, 1877.—*Tumour in the Popliteal Space*.—The patient was a boy aged 14, and was admitted on December 15th with a swelling under his left knee. The joint had, five years since, become bent, and was blistered by a surgeon; but the patient never was in any hospital before, and could not give a more complete history of his illness. —Mr. MORRANT BAKER found a large fluctuating swelling in the outer part of the popliteal space. The tendon of the biceps was spread over its posterior aspect, and it could be made, by pressure, to project considerably to the outer side of that tendon. No pulsation could be felt, but obscure fluctuation could be detected. The growth of the tumour had been slow. Mr. Baker believed it to contain fluid, and to be either a bursal tumour or a chronic abscess. Should it increase, he proposed to puncture it with antiseptic precautions, since, of course, the growth might communicate with the joint. —Mr. SAVORY stated that *primæ facie* evidence was in favour of the swelling being bursal; but bursal enlargements are rare in the popliteal space, except in connection with the semi-membranosus, nor was this tumour made tense, in the characteristic manner of distended bursæ, when the biceps was set into action. It was either an abscess or a fatty tumour, and an exploratory puncture was necessary. —Mr. THOMAS SMITH also recommended puncture, since the swelling was hard to diagnose. He believed it to be either a fatty or a fibro-cellular tumour.

*Abscess in Abdominal Walls*.—Mr. BAKER brought forward a male infant, fifteen months old, that had been ailing for three weeks. Four days ago, the mother noticed a swelling in its abdomen. It was situated in the right hypochondrium, and fluctuated on pressure. Mr. Baker believed the swelling to be an abscess. The child was examined under chloroform, and all the staff agreed with Mr. Baker's opinion, which proved to be correct, as the tumour was punctured and a quantity of pus escaped.

*Malignant Disease of the Upper Jaw*.—Mr. SMITH introduced, for consultation, a man aged 46 with advanced malignant disease of the left superior maxilla. Several teeth had come away, and a probe introduced into their sockets passed into a soft mass. The patient was in good health; none of the lymphatics below the chin were enlarged. He had a wife and several children dependent on him. As most of the surgeons present were in favour of immediate removal of the upper jaw-bone, Mr. Smith determined upon operating very shortly.

January 3rd, 1878.—*Tumour of the Scapula*.—Mr. MARSH introduced, for consultation, a man aged 41. This patient had suffered for

about nine months from severe pain about the back and shoulders, most intense over the lower part of the right scapula, where, about the time that the painful symptoms commenced, he discovered a tumefaction. This Mr. Marsh now found to be a prominent swelling, very tender to the touch, and neither hard nor distinctly fluctuating on pressure. It clearly protruded backwards from the infraspinous fossa; but it likewise appeared to extend to the lower part of the subscapular fossa; the lower part of the scapula was pushed outwards away from the ribs. There were no enlarged glands in the axilla. The patient had suffered from a sore on his penis a year ago, followed by sore-throat and eruption. Mr. Marsh proposed to make an incision into the swelling, which was probably either a subperiosteal abscess or a softening gumma. Such a proceeding would at least relieve the pain and help to reveal the true nature of the disease. The surgical staff mostly agreed with Mr. Marsh's opinion.

*Chronic Disease of the Knee-Joint*.—Mr. SAVORY exhibited in Kenton Ward a tall robust man, aged 27, with advanced disease of the knee-joint, partial dislocation of the tibia backwards, but no sinuses or reddening of the integument. The knee had been injured four years previously by a fall from a locomotive engine. It had been, the patient asserted, always more or less "bad" ever since; but he never had been an in-patient at any hospital till a few weeks ago, when he came under Mr. Savory's care. For the first time the affected limb was rested on a splint, the knee was blistered; but no permanent benefit had resulted from that treatment. Whilst Mr. Savory was detailing the above facts, the patient recognised Mr. Willett, and stated that he had been under that gentleman's care, since the accident to his knee-joint, in the outpatient department of the hospital; and remembered that Mr. Willett had detected a loose cartilage within the joint. Mr. Savory determined either to amputate the limb or excise the joint, and was personally in favour of amputation. —Mr. THOMAS SMITH recommended that a search should first be made for the alleged loose cartilage under Lister's carbolic spray. —Mr. WILLETT and Mr. LANGTON were of the same opinion. —Mr. MARSH felt certain that the joint was irremediably spoiled, whether there were or were not a loose cartilage within it. Any proceeding short of amputation would involve an useless and unnecessary risk of the patient's life. —Mr. SAVORY, though still in favour of amputation, determined on a preliminary exploration of the joint. He did not intend to make the incision under carbolic spray, since, in these cases of advanced disease of large joints, he had never seen any additional advantage in that precaution.

## NOTES ON BOOKS.

*Letts's Diaries and Almanacs*.—We have received several of Messrs. Letts's very useful diaries and almanacs; and, in a long list of various kinds, particularly notice their Medical Diary, which will be found a very handy pocket reference, containing carefully compiled information for the especial use of the profession, and prepared for noting obstetric engagements, vaccinations, addresses of assistants, thermometrical and other fluctuations, and for keeping cash accounts. It is got up in several sizes and styles, varying in price from 14s. 6d. to 24s. 6d.

DR. THUDICHUM's tractate *On Polypus in the Nose and other Affections of the Nasal Cavity, their Successful Treatment by the Electro-caustic and other New Methods* (London: Longmans) is an extremely able and careful description of an undoubtedly successful proceeding, into which he has introduced many important practical improvements. The removal of polypus according to the old-fashioned methods was a dirty, incomplete, painful proceeding; it has here received the finishing touches which render it precise, complete, and almost painless.

We cannot praise too highly the *Royal London Ophthalmic Hospital Reports*, of which part ii, vol. ix, now appears, edited by Mr. J. Hutchinson. Highly accomplished in all the departments of surgery, in none is Mr. Jonathan Hutchinson more at home than in ophthalmology; and in Mr. Nettleship he has an able disciple and colleague. It is not to the credit of our leading ophthalmic practitioners that so much of the burden of scientific ophthalmic progress in this country is laid upon the shoulders of Mr. Hutchinson: in editing and producing this journal, Mr. Hutchinson adds, however, to the many debts under which he has laid scientific surgery in this country. The contributions to this number are mainly from members of the staff of the London Hospital, whom Mr. Hutchinson has inspired with something of his own spirit of laborious study and careful research.

DR. WYNTER BLYTH's paper on the *Prevention of Rabies in Dogs* (Congdon and Board: Exeter) did excellent service in forming a correct public opinion when it appeared in the pages of a contemporary, and we are glad now to see it reprinted.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 12TH, 1878.

RELATIONS TO LIFE OF THE DISTRESS AT MERTHYR TYDFIL.

OUR readers will doubtless have been startled by the descriptions of the distress among the iron-making and coal-getting population of the town of Merthyr Tydfil. How far the present extreme suffering may have been due to mistakes in the discussion and decision of questions relating to capital and labour, it is not our province to inquire; but, seeing the statements in the public papers, and noting the report of the health-officer of the district, it may be profitable to inquire what unfavourable influences the distress may have had upon the health of the people.

It will be necessary to regard this inquiry in two aspects: the *steps* which have brought the working people of the district into so low a state of poverty and distress; and the *causes* which have conduced to the mitigation of the evils which usually follow in the train of poverty.

Prominently, these were the causes which have reduced these hard-working and thrifty people to poverty. A plethora of capital sought a means of revenue; the means in this district was the sinking for coal; coal was obtained in quantities far beyond the need of consumers; for a time, a brief time, there was an increase in the demand; but very soon the market was glutted, and, the need ceasing, labour, too highly paid for during the panic, became a drug. As with coal, so with iron. The demand for rails in America, with guarantees from "bogus" companies, gave an enormous impulse to the manufacture. Iron ore was sought for in Cumberland, Cleveland, Northampton, Bilbao, and Tharsis; furnaces were built, the ore smelted, the iron produced, and the rails rolled. But dollars were not forthcoming to pay for them; the making of rails was arrested; paper companies failed; and the iron-workers and labourers were unemployed.

Thus it has resulted, from an abuse of trade, that masters and men have been deprived, the one of the means of continuing the struggle for trade, the other of the use of those thews and sinews which they have ready for labour.

This diminution of the demand for work has been going on for three years; and the result has been the gradual but continuous diminution of the means for purchasing food. Gradually, but continuously, these men, ready to labour, have been reduced from full rations to half-rations, from half to quarter, from quarter to none. The statements published in the *Daily News* of Tuesday, January 8th, will show how the working men and their families have been reduced to the "lowest ebb of poverty and distress".

But how has this continuous lessening of the food supply hitherto acted upon the health of the people? The reports of the health-officer for 1875 and 1876, and the abstract of his statement for 1877, enable us to answer the question. In the report for 1875, it is shown that the annual death-rate, which in 1845-55 was 35.5, was reduced to 21. In 1876, it was 19; in 1877, 20 per 1,000. Thus the poverty of the people, gradually increasing, did not affect their health unfavourably.

Passing to the mortality due to special ailments, it is shown that the rates of mortality due to phthisis was reduced from 38 $\frac{2}{3}$  to 29; enteric fever, from 21 $\frac{1}{3}$  to 5 $\frac{1}{4}$ ; diarrhoea, from 8 $\frac{1}{2}$  to 1 $\frac{3}{4}$  per 10,000 of the

people. Typhus had been wholly absent from the town since the previous period of poverty in 1867.

To what is this immunity from diseases, which might be expected to spring up with poverty, to be attributed? The health-officer's reports supply the ready answers. The Local Board of Health, in twenty-five years, at a cost of a quarter of a million of money, have provided a regular system of scavenging, a perfect system of drainage and sewerage, and an unlimited supply of pure water.

The men of Merthyr have found that the provision of pure air and pure water has resulted in producing a state of health that has hitherto resisted the depressing and debilitating influences of poverty. But how long can they resist those influences? Weakened by the want of a sufficiency of food; tried by the rigour of the climate in which they reside; hopeless as to the future; the stoutest hearts must fail—their weakened health must give way.

Mr. T. J. Dyke, the able Health-Officer of Merthyr Tydfil, to whom the whole population has long felt its deep debt of gratitude, in his epitome of the statistics for 1877, has called the attention of the authorities to the necessary sequence of this continued lowering of the vital powers, and the huddling together in the miserable dwellings, graphically described by the Rector of Merthyr. These must inevitably lead to the induction of that malady, famine-fever, which, in former times of destitution, so painfully affected the inhabitants of this stricken town.

Liberal and generous as the public have been, and are yet likely to be, to the sufferers, it is, we believe, nevertheless incumbent on the local authorities to find means (even though they should be costly and unprofitable) of occupation for the able-bodied; and thus afford food for the hungry, and the means of living for the sick.

PHYSICIANS, PRACTITIONERS, PATIENTS, AND FEES.

THE question of medical fees has been raised in several places during the last few weeks. A spirited article in the *World* charges a large section of well-to-do people with the habitual practice of doing the doctor by claiming his assistance and evading his *honoraria* on all sorts of pleas of professional connections or sympathies, indirect social claims upon the medical profession, and upon the victim in particular; sometimes by sheer impudence and disreputable devices. There is no doubt that the medical profession is more largely than any other victimised by such persons. Very few people consult the lawyer with the deliberate intention of defrauding him of his fees; but it is, as most medical men have painful reason to know, a common practice among those who consult the doctor. *Accipe dum dolet* has long been a professional maxim of much worldly wisdom, and is often recommended to general acceptance. Etiquette has grafted it as an essential part of the relations of the pure physician and surgeon to his patients; and the College of Physicians of London, by prohibiting its Fellows from recovering fees by law, has indirectly intimated how considerable a part of the dignity of the medical profession they consider it to be, that such a rule should be generally adopted. Such artificial distinctions between one grade of medical practitioners and another are, however, not always easy to maintain. In these later days, mixed practice by nominally pure physicians and surgeons, time, the railway and telegraph systems, the growth of wealth, the opening of all the universities to aspirants of every grade, have done much to level class-distinctions; and, when we find in almost every town graduates holding the highest diplomas in medicine fulfilling all the minor functions of general practice amongst the poorer classes, but rising, as their knowledge and capacity entitle them to rise, to the highest exigencies of professional duty, it is obvious that such distinctions become artificial. This artificial character is in some sense aggravated by the fact that, on the other hand, eminent physicians and surgeons in the great centres of population, are habitually consulted by family clients under all circumstances and in every exigency; and that they are, from one point of view,

as much family practitioners as any general practitioner, exercising their own discretion as he does as to consultations in any particular cases, and as to the limits which they choose to impose upon their own sphere of practice. It is of course exceptional to find, as one of our correspondents from an important Northern city describes, a court-surgeon and professor engaged in club practice among the poor; but the imbroglia is still further increased by the fact that there are many physicians who make operative surgery a specialty, and some surgeons whose specialty, as in the case of skin-diseases, is essentially medical; while there are others, such as ophthalmologists, whose specialty avowedly includes both medicine and surgery in principle as well as in practice.

Thus we have found, in the correspondence now continuing in our columns, and in which eminent physicians on the one hand and leading general practitioners on the other have taken part under pseudonyms, that the functions of the two classes are by no means so easily marked off as is sometimes assumed, and that complaints arise on both sides, on very different grounds, as to the scale of fees and methods of payment. On one hand, a great physician complains that patients do not always pay their guineas on the spot; that they run up long accounts, which there is a difficulty in calling in when the sum has risen to an important amount, although it has been by their request, and to their obvious convenience, that such proceeding has been committed. A complaint also arises that the physician or surgeon is expected to spend a considerable amount of time in particular cases on the patient, in consultation sometimes with a general practitioner, and the minimum fee of one guinea is all that is tendered to him. On the other hand, a physician of no less eminence maintains that any man in the position of a Fellow of the College of Physicians, who does not demand his guineas on the spot, deserves to lose them; and a general practitioner of no small repute declares that he considers that the physician's trouble is lessened by the presence of the medical attendant, rather than increased; and that he should receive a smaller rather than a larger fee under the circumstances.

A further feature in the discussion is introduced by the letter addressed to the *Times* by "An Overwrought Patient," who there says:

"I have a bone to pick with my doctor; but I feel some delicacy in speaking to him direct, because he is a very good fellow, and occupies much the same social position as myself. Will you let me ask him, then, through you, why he never condescends to give me any items or dates in his bill, but fleeces me under the simple and comprehensive heading, 'Medical attendance'? If my tailor were to send in his account merely 'To clothes', I should have no scruple in having it out with him, should the amount exceed what I had anticipated; but, for the reasons above, I cannot so treat my doctor, and he has, therefore, an unfair advantage over me. If he would give me some details, were they only dates, he would greatly soothe, yours truly," etc.

In a spirited article in the *Daily Telegraph* of Wednesday, it is pointed out that the gentleman in question might very easily have surmounted his delicacy and asked his attendant for particulars, which would have been furnished; and, indeed, general practitioners who are in the habit of sending accounts of the kind, frequently append a printed notice "particulars furnished if required". Such particulars are, however, rarely necessary, as the tariff of visits is commonly understood from the first between the patient and his attendant, and the fees due are estimated by the number of visits. In this article, our contemporary displays a very warm and generous sympathy with the extremely toilsome, anxious, and responsible duty of the medical man, and the very inadequate remuneration which commonly awaits him. Then there is also raised the larger question of what should be the limit of *honoraria* which medical men have a right to expect. On this head, it observes that

"No sane man expects that Mr. Millais would paint his portrait for four half-crowns, or that Mr. Serjeant Parry would defend him in an action for breach of promise with a brief marked 'one gu.'; and,

although Mr. Thackeray used humorously to complain that an eminent firm of Scotch publishers once offered him the magnificent sum of eight pounds for a life of Queen Anne, he would be a bold bibliophile indeed who proposed to pay George Eliot fifty pounds for a three-volume novel. Apart from the fact that the 'worth of anything is just as much as it will bring', as Butler pointed out long ago, it must be remembered that the fee of the surgeon and the *honorarium* of the physician are due, not only for a special service rendered at a particular time, but for the application to an individual instance of the result arising from long years of study, reflection, and experience. One touch of the surgeon's lancet, or half-a-dozen words from the physician's lips, may thus have the intrinsic value of five, or ten, or it might be of fifty or a hundred guineas. The touch given with assured skill may cut the knot of a problem which has tormented us for years. The words spoken with indisputable authority may be the 'Open sesame' to the long-closed portals of health and vigour; but what do we know about the hours of anxiety and study, the painful labours, the repulsive experiences which the practitioner has gone through? What do we know of the possible poverty, obscurity, and discouragement which he has endured before he became qualified to give that magisterial touch with his instrument, or to pronounce the opinion which, humanly speaking, may well nigh be accepted as the fiat of fate?"

This is powerfully put, and explains to the public apprehension the fallacy of a strict theory of uniform fees in a manner which all can understand. The payment of medical men has, in fact, not progressed with the general rise in modern expenditure and the cost of living in modern society. The general average of payment for services of the general practitioner has, we believe, risen to a higher level during the last twenty years, and is probably still rising, and it is within the power of each man to determine whether the tariff of his visits should be half-a-crown or ten shillings; it is commonly considered, however, that no such discretion rests with the pure physicians and surgeons. Mr. Millais may charge a thousand guineas for a portrait, or a great lawyer may refuse to go into court unless his brief be marked with a minimum of one hundred guineas as a retainer, independently of the court fees at the rate of one hundred guineas a day and extra fees for consultation: a junior of the same professional "hall-mark" at the bar, and bearing the same relation to him as the assistant-physician at a hospital bears to his successful chief, will accept the same brief marked with a retainer of from two to five guineas. The physician, however, of no matter what age, eminence, health, or preoccupation by weight of engagements, is accustomed to receive all comers in his waiting-room at a guinea for each consultation, whether he be in a position comparing with that of the Attorney-General at the bar, or with that of the youngest barrister called; he must receive them, too, in strict chronological order; and it is a subject of complaint, in a recent number of the *World*, with which many will sympathise, that in the crowded waiting-rooms of highly reputed consultants such order is not always strictly observed.

It is probable that the continued discussion of this subject, in the course of the correspondence now going on in our columns, will throw some further light upon the views generally entertained in the profession on this question. To the great credit of medical men, it may be said that such discussions are always more or less distasteful, and, for our own part, we are never disposed to commence them hastily or to carry them on lightly; but in this instance, and at the present moment, we think the debate may not be useless in contributing, at least, to a clearer understanding of the relations between physicians and general practitioners and their clients. Perhaps it may tend also to improve their relations, and to leave to the physician some larger discretion in fees than is at present accorded. We are disposed to think, for instance, that the question might properly be discussed, whether it is for the benefit of the public itself and of all classes of the profession that physicians should be allowed a much larger power over their tariff and consulting fees in their own consulting rooms than is at present generally conceded; and no doubt, also, general practitioners may have something to say as to their difficulties and limitations.

## PLAGUE AND CHOLERA.

PRIVATE information from the Levant had just brought to our knowledge certain facts which give a more serious aspect to the recent prevalence of plague in North-Western Persia, when the telegraph from Alexandria flashed the news of the appearance of cholera at Jeddah, the seaport of Mecca, and in the sacred city of Mohammedanism itself. Europe, then, if the telegraphic information as to cholera be true, is now confronted with a double danger of plague and cholera, and that under circumstances where such measures of international precaution as might be possible can hardly be entertained while the war between Russia and Turkey continues. Russia is too seriously hampered in the present struggle to give such heed as she else might do to the dangers of pestilence threatening her on her Caucasian frontier; Turkey is helpless on her eastern frontier; and her great feudatory Egypt is now so gravely involved in the struggle with Russia, that her efforts to protect herself from the Indian malady must be seriously crippled.

We learn that the outbreak of plague at Resht and in the neighbouring district last year was, perhaps, the most formidable which has occurred of the several reappearances of the disease since 1873. It seems almost incredible, having regard to the sources of information on the subject, some official, which have been available, that now for the first time we should learn this to have been the case. But our information comes from a source in which we have every confidence, and it is to this effect. The Persian returns of the prevalence of the disease in Resht, at all times most questionable, were designedly made to disguise the actual state of affairs. Although a liberal allowance was made in view of this local official peculiarity—in other words, although the official returns were multiplied by from four to six—and the result accepted as a reasonable approach to the actual state of affairs, it is now stated, on good authority, that even the sextuple multiplication fell far short of the actual reality. It is idle quoting figures under such circumstances; but it is now averred that the fatality from plague in Resht last year was greater than that which occurred in Bagdad, with its much larger population, in 1872. If this, as we believe, occurred, the outbreak at Resht shows that the disease is still gathering force, and that Europe must keep on the alert in view of a probable widely diffusive explosion of the malady.

It is of much interest, with reference to the reappearance of plague, to know that in the course of last year the Sali plague appeared in the province of Kumaon, Northern India. We are indebted for this interesting information to the President of the Epidemiological Society, Surgeon-General John Murray, M.D.

We refrain from observation on the reported appearance of cholera in Western Arabia until further and more detailed news is received; but it may be remarked that, in the recently published annual report of the Local Government Board, Mr. Selater-Booth states that that department of the Government had been watching with some anxiety, during 1876-77, threatenings of a wide spread of cholera beyond India, and especially certain extensions beyond the northern frontier.

## BIRMINGHAM PROVIDENT DISPENSARY.

A HISTORY of the many good causes which have been ruined or retarded by the perversity or narrow-mindedness of their promoters, would form a large and instructive volume. We see reason to fear that a projected provident dispensary in Birmingham may form another item in the catalogue of such misfortunes. A few weeks ago, we drew attention to the fact that the promoters had failed to take counsel with the two classes chiefly, we may say solely, interested in the success of the scheme; viz., the doctors, and their patients the artisans. Since then, the "Trades Council" of Birmingham appointed a deputation to wait upon the promoters' committee and to explain the views of the artisans upon the subject. We learn now that the deputation was very courteously received, and their explanations attentively listened to. One of the points urged by the deputation was that the working classes ought

to be represented upon the Provisional Committee. To this the Committee replied that "it was itself only provisional"; but, nevertheless, "after the interview, the members of the deputation were added to the Committee": a step strictly in accordance with the powers accorded to the Committee by the town meeting at which it had been appointed. It is superfluous to remark that this is a step which ought to have been taken spontaneously by the Committee at its first meeting; it is, at the same time, satisfactory to learn that the Committee is not impervious to reason, and may be compelled by gentle pressure to do right.

It yet remains for this body to pave a way to a successful issue by consulting the representatives of the medical profession. But as yet, although our former remarks on this point were quoted at length by the leading local paper, the *Birmingham Daily Post*, the organ of the local Liberal party, the Committee has failed to discharge this its primary duty. It is true that, by now taking this step, the Committee would tacitly confess that it had at first been guilty of a blunder in with scantest courtesy, slighting the offers of co-operation which were tendered to it by the Council of the Local Branch of our Association. This blunder has already borne fruits. The Committee has made advances to secure the countenance of the three principal medical charities (the General Hospital, the Queen's Hospital, and the Dispensary), and in each instance without success. Was it likely that the medical officers of these bodies, nearly all of them present or former officers of the Branch, and therefore conversant with the feelings and views of the profession in the district, could sympathise with a body which had so studiously and ostentatiously informed the profession that its advice and opinion were of no account?

We hold, and always have held, that judiciously founded and governed provident dispensaries will advantage both the artisans and the profession, and it is therefore with regret that we see the Birmingham scheme threatened with failure by the faults or omissions of some of its promoters. Is it too late for some of the larger minded of them to rescue it?

---

HERR RUHMKORFF, whose name is familiarly known in connection with an electric apparatus, died on December 21st, at the age of seventy-five.

---

DR. LANG of Southport was killed on Saturday by an explosion of gas in his dwelling-house. The explosion, which caused considerable damage to the building, was the result of an attempt to trace a leakage of gas with the aid of a light.

---

THE *Times* correspondent, writing under Bucharest under date of January 8th, says: The Russian Sick and Wounded Society of London has become, in spite of itself, a Turkish Aid Association for the benefit of the Moslem sufferers from Plevna. Their hospitals at Turn Magurelle and Putine are filled with Turkish wounded, and among the surgeons who assisted in the care of the wounded of Osman Pacha's army after the fall of Plevna, Drs. Maturin and Davis were noted for their labours. Prince Charles of Roumania personally thanked the Society's surgeons for their services to the wounded prisoners.

---

THE foundation-stone of the Hahnemann Convalescent Home at Bournemouth was laid last week by the Lord Chancellor, who complimented the subscribers on dedicating the building to the name of Hahnemann. He well knew the almost persecution which was waged against Hahnemann during his life, but he survived it; and in the direct benefit which his system had contributed, and in the indirect benefit it had conferred in stimulating the growth of other systems, Hahnemann would be looked upon as one of the greatest benefactors we had ever had. We commend to Lord Cairns, who is probably as ignorant of medical subjects as he is learned in the law, the newly-published homœopathic journal entitled the *Organon*, from which he will learn what the doctrine of Hahnemann really was, and what its teaching and influence are.

A TELEGRAM has been received from Consul Zohrab advising the immediate recall of the English surgeons at Erzeroum. They are subjected, he says, to so many privations and perils from the pestilential condition of the town, that he considers they ought not to be allowed to stay.

ONE of the latest acts of General de la Marmora, whose decease has caused such universal grief throughout Italy, was to apply a large part of his great fortune to endow the hospital of Turin, the rest being applied to relieve the poor of Florence and to subsidise industrial efforts in his native town of Biella.

#### THE HOSPICE OF ST. GOTHARD.

FROM an official document, we learn that this famous "Traveller's Rest", between October 1st, 1876, and September 30th, 1877, gave shelter to 15,651 travellers, to whom 52,783 rations were gratuitously distributed, as well as a certain quantity of clothing. One hundred and forty-three sick persons were also treated there during more or less lengthened periods. The total expenses amounted to 13,860 francs 45 centimes (about £554); and the receipts to 13,507 francs 75 centimes (about £540), showing a deficit of 342 francs 70 centimes; but the cantonal governments and private individuals will, as they always do, come to the help of this useful institution, which welcomes the indigent of all nations without distinction.

#### ANTI-VIVISECTION MEETING AT KILBURN.

THE National Association for the Total Suppression of Vivisection held a meeting at Kilburn on the 4th instant. In addition to the usual arguments, one speaker mentioned that a class of students had been invited to observe how a cat could walk a few steps after having its heart cut out. We should like to know where this remarkable experiment was performed. Dr. T. Morton entered his protest against the policy and objects of the Society, and moved as an amendment: "That this meeting, relying on the report of the Royal Commission, and being satisfied with the present law, deprecates further agitation on this question." A few weeks ago, we urged medical men to attend these meetings and to point out, from the text and evidence of the report of the Royal Commission, how misleading are the monstrous falsehoods and fanatical nonsense which are generally put forward. Those who, like Dr. Morton, do so, deserve great credit; for it is no easy matter to stand up, perhaps single-handed, in an assembly of enthusiasts who have been brought together, not to hear reason, but to express a foregone conclusion derived from a long course of exciting calumnies. Still, it is our duty to disseminate correct information on this subject and to enlighten public opinion; for none can understand it in all its bearings so well as medical men, and the discussion has provoked an outburst of virulent nonsense which ought not always to pass uncontradicted.

#### HARVEIAN SOCIETY OF LONDON.

THE annual meeting of this Society was held on Thursday evening, January 3rd. The rooms have recently been redecorated, and presented a pleasant appearance. The usual Council meeting was held before the *conversazione*, and it was found that the finances of the Society were in a most healthy condition. In the absence of the Ex-President, Mr. Carr Jackson—who retired during the session in consequence of impaired health, but who wrote to say that he is now recovering—the chair was taken by Mr. W. F. Teevan. By the exertions of the secretaries and a committee, the meeting was of a very attractive character. Telephones communicating between different rooms were exhibited in action all the evening, and were surrounded by crowds during the whole time. A volume of photographs of "Bulgarian Atrocities" was lent by Mr. Ernest Hart, and excited much attention. Microscopic objects of great interest were exhibited by Dr. Ferrier, Dr. Mahomed, and Mr. Henry Power. Paintings and other objects of art were shown by Mr. Seymour Haden, Dr. Farquharson, Dr. Cheadle, Dr. Braxton Hicks, Dr. Evershed, and

others. A new feature was added in the form of some first-rate instrumental music. The attendance was much larger than was ever known before, and among the visitors were the President of the Royal College of Physicians, Dr. J. C. Bucknill, Mr. Curling, Dr. Crichton Browne, Dr. Langdon Down, Dr. Lockhart Robertson, Dr. Broadbent, and other prominent members of the profession. The following is a list of the newly-elected officers of the Society. *President*: W. M. Graily Hewitt, M.D. *Vice-Presidents*: W. B. Owen, Esq.; J. Hughlings Jackson, M.D.; John Easton, M.D.; E. Symes Thompson, M.D. *Treasurer*: Henry Power, Esq. *Secretaries*: Henry Sewill, Esq.; J. Milner Fothergill, M.D. *Council*: G. Eastes, M.B.; R. Farquharson, M.D.; A. Meadows, M.D.; P. Boulton, M.D.; S. Felce, Esq.; F. J. Gant, Esq.; G. Field, Esq.; T. C. Jackson, Esq.; W. Cheadle, M.D.; G. G. Bantock, M.D.; N. H. Stevens, Esq.; A. Wiltshire, M.D.

#### A CENTENARIAN.

DR. E. P. CLARK writes to the *Philadelphia Medical and Surgical Reporter* that Mrs. Elizabeth Allen died in Charleston, Rhode Island, on November 28th, at the age of one hundred and five years and five months. She was born on June 22nd, 1772. Her mind and memory remained undimmed until the last. She remembered the burning of New London by the British in 1781. She also remembered the birth of her brother, which occurred on March 18th, 1772.

#### ALLEGED FIRING ON WAR HOSPITALS.

INTELLIGENCE having been received from Rustchuk that, notwithstanding the existing agreement to respect hospitals, Russian shells from Giurgevo struck the hospitals at Rustchuk, the English surgeons, at the risk of their lives, conveyed the Turkish wounded to the casemates. In reply, it is alleged that the Russians explain their firing upon the Turkish hospital by a report that upon a shell accidentally falling upon it, three hundred armed Turks rushed out, whereupon they came to the conclusion that the Turks were wrongfully sheltering their barracks under a hospital flag, and so continued their fire upon the building. It is, however, contended that the Russians, at a distance of a couple of miles, could not see whether these two or three hundred poor wretches were or were not armed, and that, admitting their statement to be true, it is explained by the fact that the arms of the wounded are, in the majority of Turkish hospitals, placed near the bed's head, in order that upon recovery, each man may have his own arms, and soldiers finding themselves attacked would naturally catch them up in rushing out.

#### SYPHILINUM AND PSORINUM.

WE have received No. 1, vol. 3, price 4s., of the *Organon*, a quarterly "Anglo-American Journal of Homoeopathy" (Liverpool). Homoeopathy has died a natural death in the "British Homoeopathic Society", where the name only survives, which is now (to quote Dr. Wyld, the Vice-President) rather a Society "only too happy to enrich our therapeutics from every available source"; proving the truth of the saying, "Men are usually better than their creeds". Dr. Wyld adds that "every member of this Society, when on a cold day he warms first his front and then his back at the fireside, so far gives *a priori* and *a posteriori* reasons for not being a homoeopathist". Then, "Why—great reason why," cries Dr. Skinner, the senior editor of this new review, "call yourselves the British Homoeopathic Society?" And to that question the British homoeopaths must find it rather difficult to give a satisfactory reply. Dr. Skinner's "Anglo-American Review" is, however, homoeopathy pure and simple. He is at least logical and sincere. He has gone back to the fountain-head, and draws his inspiration from the Hahnemannian *Organon*; and here we find at least the real article. Hahnemann's great pathological discovery was, that where it did not lie at the bottom of the disease, we would find syphilis, and every disease must be cured by its *similimum*, potentiated by dilution; and here we accordingly have a "stupendous cure" of caries of the spine by that "silent but miracle-working dynamis" "the nosode *sypiliticum*". "Not that *sypiliticum* is

homœopathic to all cases of caries; it can only be homœopathic to the variety arising from syphilis, not from psora." *Syphilinum*, like *psorinum*, is, it appears, euphemistically "a diluted and potentised product of disease"; at which, however, it seems, some of the "unco guid" turn up their noses and eyes with horror. The results of a fragmentary proving of *psorinum* is described by Dr. Forster in this journal as follows. "A patient took *psorinum* c. m. (Swan). His throat became covered with spots the size of an ordinary pillule and larger, covered with a cheesy-looking creamy top, a pink circle round the base, and some of them looked as if mortification was setting in; they turned black, but there was no factor. The throat-symptoms were worse from hawking up, worse from gargling with cold water, and always better from no beer." This is the real article; here runs the fountain (not altogether undefiled) of homœopathy as Hahnemann discovered and taught it; and no one who wishes to study homœopathy should fail to take an opportunity of dipping into this psychologically interesting volume. Excellent fooling it might be thought, if it were not strange reality.

#### SMALL-POX AT HARWICH AND IPSWICH.

WE have gathered, from authoritative sources, full particulars of the outbreak of small-pox at Harwich and Ipswich, which is, not without reason, creating great alarm in those towns. We are informed that the first case occurred in Harwich, on October 9th, and that Mr. Evans, the medical officer of health, reported the case to the public health authorities, and at the same time strongly recommended isolation. That recommendation was unfortunately disregarded until the middle of December, when the authorities saw the necessity of adopting it; but it was not until December 24th, and when upwards of forty cases and some deaths had occurred among a population of between six and seven thousand which overcrowds the town, that the requisite accommodation was found. In the meantime, the disease rapidly spread, more particularly in the narrow courts and alleys, which are so common in old seaport towns, and in the overcrowded houses let out to more than one family. At the end of December, Dr. Blaxhall of the Local Government Board went down, and assisted the sanitary authority by selecting a row of nine empty cottages for use as a temporary hospital. The health committee at once set to work, had openings made in the partitions between the bedrooms of the cottages, and furnished the upper part for the reception of forty patients. The hospital was opened for the reception of patients on January 1st, Mr. Sall being appointed to take medical charge for £150 for three months, Mr. Evans, the medical officer of health, having tendered his resignation, owing to the utter disregard which had been paid to his advice with regard to isolation, which, he reasonably thinks, had it been adopted, would have prevented the spread of the disease at the onset, and believing the course he has taken due to himself and to his professional reputation. Revaccination is being to some extent carried out by the practitioners of Harwich and Dovercourt, but not in the systematic manner it ought to be, under the direction of the sanitary authority. For some years, the provisions of the Vaccination Act have not been efficiently enforced in Harwich, and it is principally owing to this neglect that the present outbreak has taken place. The disease was brought into Ipswich on two or three different occasions; each case, however, was at once removed to the Fever Hospital, and precautions against infection taken, so that no further spread took place in any one instance. The borough of Ipswich has, with commendable spirit, been provided with the means of dealing with infectious disease, for some time possessing a hospital. Nothing more could be desired to prove that it is within the power of the sanitary authorities to prevent any serious spread of disease, than the fact that, on ten different occasions during the year 1877, small-pox has been introduced into Ipswich from London and other places; and, in every case where isolation, revaccination, and disinfection were strictly carried out, the disease was not communicated to a second person. Ten cases removed from ships in Harwich harbour have been under treatment in the

Ipswich Fever Hospital. On December 13<sup>th</sup>, two cases were reported in deep-sea fishing-smacks belonging to Harwich. They were at once removed to the hospital, a distance of twelve miles, and the smacks were fumigated and kept in quarantine four days. On December 24<sup>th</sup>, the *Volo* returned with three sickening, who were at once removed to hospital. On December 25<sup>th</sup>, four more were removed, and on the 29<sup>th</sup> one was taken into hospital; the three remaining of the crew, whose revaccination had begun to take, escaped. The disease in all these cases was of a very mild and modified type, the marks of the vaccination of childhood being of a very large and distinct nature. Not one of them had been revaccinated. The other ship, the *Alice*, with thirteen hands, which had undergone the same treatment as the *Volo*, returned from sea at the end of fourteen days after the first case had been removed from her, with all hands well, no one else having contracted the disease. The infection was taken on board these boats by one of the apprentices, from each going to his lodgings in Harwich, small-pox being in the house at the time.

#### DEFORMITIES AND REFORMATORIES.

THE prospects of reformation would be narrowed if it were to be considered only possible for those who are in sound wind and limb. Mr. J. B. Aspinall, Q.C., the Recorder of Liverpool, in ordering a boy to be sent to a reformatory, said it had been stated that the authorities would not admit the lad, as he had lost one of his feet. Their refusal to take boys for whom such places were most necessary, was unreasonable and unkind. If they continued to do so, it would be a strong reason for the Government taking them into their own hands. Children with one eye had been refused, but surely people who received substantial assistance from Government ought to be able to take children who most required the benefits of those institutions. Idiots and lunatics have been found susceptible of moral training, and we do not certainly consider the reformatory authorities entitled to treat persons suffering from minor infirmities as outside the pale of reformation.

#### M. RASPAIL.

OUR Paris correspondent writes: One of the most remarkable characters of the present century has just departed this life, in the person of François Vincent Raspail, he having nearly completed his eighty-fourth year. The name of Raspail is well known throughout the civilised world as a great political agitator, but perhaps it is as well known in connection with the peculiar system of therapeutics he endeavoured to introduce into popular practice, the basis of which is camphor, which he extolled as a panacea for all diseases. One of his sons, C. Raspail, an "Officier de Santé", keeps an open dispensary, which is well attended, and where camphor in various forms is prescribed for internal and external use.

#### OUR CANAL POPULATION.

ON the 1st instant, the Act 40 and 41 Vict., c. 60, came into operation, for the passing of which the credit is mainly due to Mr. George Smith; and its object is to remedy the evils exposed by inquiries made existing among our canal population, who hitherto were outside the jurisdiction of any local authority. The Act gives the Local Government Board power to make necessary regulations so that no canal-boat shall be used as a dwelling that has not been registered, the master and owner being each under a penalty of twenty shillings for any breach of this clause; they are also empowered to fix the number, age, and sex of persons to be allowed to dwell in the boat, having regard to space, general healthiness, separation of the sexes, and convenience of the boat. The sanitary inspection and power to prevent the spread of disease to be confided to the authority whose district abuts on the canal on which the boat is accustomed to ply; and the boat is also to be registered within a school district for the purposes of the Elementary Education Act. In the two last matters, the Act is very stringent; and to remove any difficulties that might arise in the education of the children, the Act empowers any owners of canals or canal-boats to establish and maintain schools to educate the children of persons em-

ployed in canal-boats, and also to lodge and maintain them, providing that such maintenance be not gratuitous. The rules for practically working the Act will be laid before Parliament soon after its meeting, and put into full force before the end of the year.

#### THE HEALTH OF LONDON.

THERE were 2,878 births and 1,892 deaths registered in London last week, the births having exceeded by 172, and the deaths by 135, the average numbers. The annual rate of mortality from all causes was 27 per 1,000, calculated upon the population in the middle of last year, which is estimated at 3,577,304 persons. Last week, 26 persons died from small-pox in London, 16 of the deaths occurring in Metropolitan Asylum Hospitals, and 10 in private dwelling-houses. Of the 26 fatal cases, 13 were certified as unvaccinated, and 7 as vaccinated. The number of patients in the Metropolitan Asylum Hospitals, which had declined to 137 in the beginning of October, afterwards steadily increased to 316 and 309 at the end of the last two weeks of the year, and further rose during last week to 374, the highest number since the middle of August last; 129 new cases were admitted during the week. As the result of an analysis of the waters supplied to the metropolis and some of its suburbs during December, Dr. Frankland reports that the water delivered by the five companies drawing their supply from the Thames was "much polluted by organic matter, some of which was of most objectionable origin"; although the water furnished by four of these five companies had been efficiently filtered, it was in each case "quite unfit for dietetic purposes". The Grand Junction water was slightly turbid, and contained moving organisms. The Lea water, delivered by the New River and East London Companies, had been efficiently filtered, but showed considerable organic pollution, although it was in this respect superior to the Thames water supplied by the other companies. The waters distributed by the Kent and Colne Valley companies and by the Tottenham Local Board, drawn from deep wells in the chalk, was of the usual excellent quality. At the Royal Observatory, Greenwich, last week, the mean temperature was 43.9 deg., and 7.0 deg. above the average in the corresponding week of sixty years. The mean showed a marked excess on each day of the week.

#### THE WEEKLY RETURNS OF THE REGISTRAR-GENERAL.

THE Registrar-General states that the weekly returns for 1878 will contain, as they did in 1876 and 1877, information relating to twenty-three of the largest cities and towns of the United Kingdom; the aggregate population of these twenty-three towns in the middle of 1878 is estimated at 8,373,953 persons. The returns will also, as heretofore, show weekly vital statistics relating to the London Outer Ring, the population of which, in the middle of this year, is estimated at 872,711 persons. Thus the weekly returns during 1878 will relate to an estimated population of 9,246,664 persons residing within the United Kingdom. The weekly returns will, moreover, through the courtesy of various authorities abroad, contain weekly vital statistics for twenty nine large cities situated in the four quarters of the world, and having a population of about twelve millions and a half of persons. In the middle of this year, it will be seven and a quarter years since the last census enumeration in 1871. The estimated population of each of the English towns, except Nottingham, Salford, and Oldham, for want of a more trustworthy basis, is based upon the observed rate of increase prevailing between recent census enumerations. The estimates for Nottingham, Salford, and Oldham, have, however, been specially revised with the aid of local information as to the rate of increase of inhabited houses, proving to the satisfaction of the Registrar-General that the rates of increase in those boroughs since 1871 have considerably exceeded the rates which prevailed during the preceding ten years. From the beginning of this year, the returns for Nottingham will relate to the new boundaries of that municipal borough, as fixed by the Nottingham Borough Extension Act of last session.

## SCOTLAND.

THE managers of the Edinburgh Royal Infirmary report that they expect the new Infirmary will be opened by the end of next year.

DR. GUNN, a medical practitioner of Forres, dropped down suddenly and died in his house, last Saturday evening. The deceased, who was a graduate of Edinburgh University, and was at one time house-surgeon to Gray's Hospital, Elgin, had been in practice in Forres for about ten years, where his ability and kindness gained him general esteem.

DURING the past year, 86.37 inches of rain fell in the Greenock district, compared with 62.62 inches during 1876. The heaviest rainfall in any single month during 1877 was in November, when 11.38 inches fell. The lowest fall was in September, when 3.01 inches were registered.

THE public health returns for the burgh of Leith, during 1877, show that there has been registered 1,153 deaths during the year, of which 459 were of children under five years of age, and 94 were the result of zymotic diseases. The death-rate for the year was equal to an annual mortality of 22 per 1,000. Typhus fever had been fatal in 10 cases, typhoid in 24, diphtheria in 12, whooping-cough in 34, scarlatina in 7. The number of births during the year was 2,141; 1,102 males and 1,039 females. There were 108 illegitimate births.

THE trustees of the late Mr. Robert Napier of Shandon have allotted the following donations out of the fund left by the testator for charitable purposes: to Glasgow institutions—Royal Infirmary, £500; Western Infirmary, £500; Eye Infirmary, £100; Deaf and Dumb Society, £100; Association for the Relief of Incurables, £100; Convalescent Home, Lenzie, £100; Maternity Hospital, £100; and several others in the same amount, reaching a total of £2,000—and to Dumbarton, for benevolent and charitable purposes, the sum of £1,000.

#### CONTAMINATED WELLS.

TYPHOID fever has been for some time past prevalent in the neighbourhood of Wester Loan. Milnathort, and several of the cases have proved fatal. The Local Authority has had samples of water from two adjacent wells analysed by Dr. Stevenson Macadam of Edinburgh, the result being that both were found to be highly contaminated with decomposed organic matter. One of the wells has been shut up, and the use of the other discontinued, pending a thorough examination.

#### MUNIFICENT DONATION.

THE directors of the Western Infirmary, Glasgow, have been informed that, by the will of Mr. John Freeland, who died at Nice on the 25th of last month, a sum of £40,000 has been bequeathed to the institution. Since the opening of the Western Infirmary, a year or two ago, there has been a constant struggle to raise sufficient funds to carry on the institution, and at the present time the income has fallen short of the expenditure by £1,000. By the terms of the deceased gentleman's will, the £40,000 has been left exclusively for building purposes. The necessity, therefore, for increased funds is very great, as a larger number of patients than can be accommodated at present will afterwards have to be treated. Mr. Freeland, who has resided for several years at Nice, on account of his health, was a well-known Glasgow cotton-merchant.

#### THE SCOTTISH POOR-LAW.

FROM the annual report of the Scottish Board of Supervision for the year 1877, just published, we gather that the number of paupers of all classes, including dependents, in receipt of relief on the 14th of May last year, showed a decrease of 2,018, compared with that day in the preceding year. The total number was 100,640, being in the proportion of 2.8 per cent. of the population. The Board have completed

the arrangements for the distribution of the twenty-ninth Parliamentary grant of £10,000, in aid of medical relief to the poor in Scotland. The whole sum expended on medical relief of the poor in all parishes in Scotland, whether participating in the Government grant or not, was, according to the annual reports of the inspectors, £37,400, which is equal to a little over twopence halfpenny per head of the population in Scotland in 1871. It is noted that, in the county of Caithness, there are two poor-houses, with accommodation for 200 inmates, while the largest number in them during the past five years was 25, and the average 20; but the Board have been unsuccessful in endeavouring to induce the parochial boards to place their arrangements for poor-house accommodation on a more economic footing. In the Parliamentary grant in aid of the cost of maintenance of pauper lunatics, the aggregate amount distributed was £65,470. The Board reports that they have approved of the sites and plans of new hospitals to be erected by the following Local Authorities, viz., site and plans of a common hospital at Wishaw and at Inverness, and site for a hospital at Bothwell.

## IRELAND.

THE total proceeds of the bazaar, lately held for the Dublin Orthopaedic Hospital, amounted to £143 6s. 10d.

AT a meeting of the Dundalk Board of Guardians, on last Monday, a superannuation allowance of £50 *per annum* was granted to Dr. Massy, late dispensary medical officer.

DURING the December quarter, there were registered in Dublin 147 deaths from measles, being an increase of 108 over the corresponding quarter of the previous year. In Cork, during the same period, 96 deaths from measles were recorded.

MR. J. F. WOODROFFE having taken a Double-First at the recent examinations in Trinity College, Dublin, for Bachelorship of Medicine and Surgery, has received his degree, in accordance with precedent, free of all the usual charges.

DURING the September quarter, the deaths of twelve persons, stated to have been aged 100 years or upwards, were registered in Ireland. Of these, three were returned at 100 years; one at 101; two at 102; one each at 103 and 104; two at 105; one at 106; and one at 112 years.

### HEALTH OF BELFAST.

AT the monthly meeting of the Belfast Town Council, held on the 1st instant, the report of the Sanitary Committee was read, from which it appears that, during the five weeks ending December 27th, the deaths registered showed an increase with the preceding four weeks from typhus and enteric fevers and measles, and a decrease from scarlet fever and diarrhoea.

### THE CHARGE AGAINST DR. O'HARE OF BELFAST.

THE hearing of this case, to which we referred last week, was resumed on the 5th instant, and, after some evidence had been given, was adjourned to the 11th instant, for the presence of an officer from the Superior Courts in Dublin. We understand that Dr. O'Hare is a graduate in Medicine of the Queen's University in Ireland, and a member of the College of Surgeons of England.

### ST. MARK'S OPHTHALMIC HOSPITAL.

THE bazaar in aid of this hospital is to be held in the Exhibition Palace, Dublin, on January 24th and 25th, under the patronage of Her Grace the Duchess of Marlborough and other influential ladies. It is desired to form a building fund for the erection of separate and isolated wards, for the reception and treatment of infectious and contagious diseases of the eye. Under the existing limited arrangements, such cases, which are a prolific source of blindness in Ireland, have to be

altogether excluded from the hospital. It is to be hoped that the governors of this deserving institution—founded, as our readers are aware, by the late Sir William Wilde—will be liberally supported in their laudable efforts. The architect estimates that the necessary buildings can be completed for a sum of £4,000.

### HEALTH OF DUBLIN.

DURING the past month, the mortality in Dublin has been alarmingly high. The Superintendent Medical Officer of Health, Dr. Mapother, reports that for the past few weeks the death-rate has been 29.9 per 1,000 yearly, one-twelfth above the average of the ten previous Decembers. Measles and bronchitis have been the chief cause of this excess; the main promoting causes being, in his opinion, climatic conditions, wretched house accommodation, scanty clothing, insufficient food, and intemperance. Dr. Mapother also gently hints at certain other causes of disease, the remedies for which are within the control of the Public Health Committee of the Corporation, whose officer Dr. Mapother is, but suggests no means of carrying such remedies into execution. From an able report lately issued by the Sanitary Association, it appears that year by year the death-rate of Dublin has been gradually increasing. From an average during the previous ten years of 27.9 per 1,000, it rose in 1877 to an average of 28.6 per 1,000; and from the fifth place in point of mortality, among thirteen large towns, to the second. Notwithstanding, it is to be observed, that in calculating the death-rate for the past year, the deaths of persons admitted into public institutions have been for the first time omitted. In connection with the health of Dublin, it may be noted that measles and small-pox are still prevalent in the city. No fewer than sixteen cases of the latter disease were under treatment in Cork Street Fever Hospital last week. Twenty-three cases were admitted during the month of December. Notwithstanding this prevalence of the disease, there seems to be a remarkable apathy as regards the necessity for vaccination. The Registrar of one of the city dispensary districts reports that, in his district, there are one hundred and fifty-eight children over six months unvaccinated.

### CORONERS' INQUESTS IN IRELAND.

AN inquest held in Dublin on the 2nd of January illustrates the unsatisfactory way in which inquests may be conducted, even by the most experienced coroners. Dr. White, city coroner, held an inquest on the body of an artist well known in Dublin. The body, it appears, was found in a tank in the deceased's own house; there were about nine inches of water in the tank, which measured eight feet long, three feet wide, and sixteen inches deep, and was, therefore, a wide and shallow vessel. The body lay with the head downwards in the water. The evidence consisted of a statement by a window-cleaner, who found the body in the position indicated, with the legs stretched out and stiff. Dr. James Brady was the only medical witness examined, and his evidence related solely to what he knew of the previous health of the deceased. The coroner stated the only question was whether death was caused by disease or by accident; it was "quite clear" that it was not suicidal. The coroner also said, "out of respect to the feelings of the relatives, in such cases *post mortem* examinations should, if possible, be avoided, and in this case there would be evidence enough without it". We demur altogether to the statement of the coroner there was absolutely no evidence as to the cause of death; the fact of a body being found in water is no evidence of drowning, yet the jury returned a verdict of "death by accidental drowning". The gentleman may have been murdered and thrown into the tank; or been poisoned by himself or anyone else, and have fallen or been thrown into the water; and, lastly, he may have died suddenly from some obscure chronic disease. We say distinctly that there was no evidence, in the absence of a *post mortem* examination, to justify either the coroner's remarks or the verdict of the jury. We should be very much surprised indeed to hear that the relatives of the deceased objected or would object to a *post mortem* examination, when such was absolutely necessary to clear up the mystery connected with the death of their friend.

## WILLIAM STOKES, M.D., F.R.S.

It is with profound regret that we record the death on the 7th instant, in his seventy-fourth year, of this most distinguished ornament of Irish medicine. Since his resignation, in 1875, of the post of Physician to the Meath Hospital—a hospital which, during his fifty years' tenure of that office, he had done much to render famous—he had to a great extent retired from the active duties of his profession. He was sorely tried by a comparative failure of nervous power in his lower limbs, and last November had an attack of apoplexy, which left him hemiplegic. Up to almost the last, however, his vigorous mind retained its wonted clearness and even hilarity. His sun in its setting displayed much of the splendour of its meridian career.

William Stokes was one of a family in whom genius is hereditary. He was the second son of Dr. Whitley Stokes, also a distinguished physician, a Fellow of Trinity College, Dublin, and Professor of Natural History in the University. Whitley Stokes resigned his fellowship in 1830, on being appointed Regius Professor of Physic: an instance, the third only on record, of a medical Fellow having filled this high professional and academic position.

The subject of our memoir was born in 1804, and even in his early years gave evidence of the possession in no small degree of remarkable ability. His medical studies were pursued in the University of Edinburgh, where his thoughts were much influenced by the teaching of "the illustrious Alison," and where he graduated M.D. in 1825, the same year as his distinguished fellow-citizen Sir Dominic Corrigan. The following year (1826), at the early age of twenty-two, Stokes was appointed Physician to the Meath Hospital and County of Dublin Infirmary, having succeeded to his father's place in that institution. Here he had the renowned Graves as a colleague, with whose views as to the urgent necessity of a complete reform in the manner of clinical teaching as then pursued, he fully coincided, and co-operated in the most active way.

Dr. Stokes's literary labours commenced at an early age. In 1825, when but twenty-one, he published in Edinburgh *An Introduction to the Use of the Stethoscope*. This work, a small octavo of two hundred and twenty-six pages, is dedicated to his friend William Cullen, M.D., the well-known Edinburgh lecturer on Anatomy and Physiology. Very soon after his appointment to the Meath Hospital, he contributed several clinical papers and clinical lectures to the periodicals of the day. Some of the latter, forty-four in number, which first appeared in the *London Medical and Surgical Journal* in 1833 and following years, were collected and published at Philadelphia in 1837, under the title of *Lectures on the Theory and Practice of Medicine*. In the same year (1837), he brought out his famous work on the *Diagnosis and Treatment of Diseases of the Chest*, which at once secured for him the reputation of being one of the most scientific and observant practitioners of the day.

The first number of the *Dublin Journal of Medical and Chemical Science* (subsequently the *Dublin Quarterly*, and now the monthly *Dublin Journal of Medical Science*) appeared in March 1832, and was edited by Dr. (now Sir Robert) Kane. "After the appearance of the first two or three numbers, Dr. Kane had associated with him, in his editorial capacity, Drs. Graves and Stokes." Kane resigned his connection with the *Dublin Journal* in 1834, and Graves and Stokes continued as editors up to the year 1842. During this period, several valuable communications appeared from Stokes's pen in the pages of the journal, either as original articles or in the reports of the Pathological Society of Dublin, of which he was Secretary, and which was established by Stokes and his brother-in-law (the late Professor R. W. Smith) in 1838. He also contributed several well-known articles to the *Cyclopædia of Practical Medicine*, as well as numerous papers to the *Dublin Hospital Reports*, *Dublin Hospital Gazette*, and *Transactions of the Association of the King and Queen's College of Physicians in Ireland*.

In 1855, Stokes published his classical *Treatise on the Disease of the Heart and Aorta*: a work which may be truly said to have in a great measure laid the foundation of the accurate knowledge now possessed of such affections. And so recently as the year 1874 he published a volume of *Lectures on Fever*: a subject upon which he is justly regarded as one of the greatest authorities, and the rational and now generally adopted treatment of which disease he was, with Graves, the first to inculcate.

All of Stokes's writings are original and unique. With marvellous

precision, he avoided to a great degree speculating on those subjects upon which he already saw the that hand of scientific progress was being laid; and so they remain valuable for all time. The hand that touches them will spoil them; it could add nothing to them, and might take much from them. The clinical facts are there, as models of observation and patient research. But it was chiefly as a teacher of medicine at the bedside in the wards of the Meath Hospital—to which famous institution he was, as we have seen, physician for half a century—that he especially shone. Those who had the advantage of being his pupils—and they may be reckoned by hundreds—can best testify as to the valuable nature of the instruction he lucidly imparted to them. It is sufficient for us to say that they tell us his method was admirable; his investigation of a case most thorough and painstaking; his diagnosis searching and accurate; his prognosis—always guarded—at times most wonderful in its exactness; his treatment thoughtfully and skilfully planned, and confidently carried into effect. His great object in teaching medicine was to make his pupils practical men, to stimulate them to original investigation, and to make them feel that he himself was in all cases their fellow-student.

As a hospital physician and teacher, Stokes's most conspicuous characteristics were the profound accuracy and painstakingness of his observations, and the fidelity of his records of disease. Truth and accuracy of detail marked all his clinical work, and stamped an imperishable value on all his published writings. As a teacher, his singular but characteristic grace, his courteous bearing, his philosophic earnestness, his extraordinary attainments, and the felicity of language in which he addressed the students, combined with his serious gravity of manner, were most effective and impressing. He was always proud of the professional success and celebrity of his pupils, and loved to dwell on the essential feature of the clinical teaching in the Meath Hospital, which fostered self-education and self-reliance by making the student responsible for the care of individual patients.

Stokes was one of the first men in this country who gave an impetus, by example and precept, to the study of the all-important and noble subject of the prevention of disease. His labours in this field alone are worthy of the most signal recognition. It was mainly due to his influence, we believe, that the University of Dublin established in 1871 the Diploma in State Medicine for those of its graduates in medicine who make a special study of the extensive range of subjects connected with the science of preventive medicine, and who pass a searching examination therein. This far-seeing step of the Irish University has met with general approbation from scientific men and statesmen; and its example has been followed by the more ancient as well as by the more modern sister universities of Great Britain. The establishment of an intimate connection between the state and the medical profession was an object Dr. Stokes had much at heart. Always most solicitous for the honour and independence of his medical brethren, and, at the same time, a far-sighted and ardent sanitarian, he perceived the advantages to be derived by both bodies from such a desirable union. In the establishment of the Medical Department of the Privy Council and the appointment of a medical member of the Local Government Board, this has to some extent been accomplished. Much, however, yet remains to be done, as is evident from the collapses which are of such constant occurrence in the execution of the sanitary laws.

Dr. Stokes's efforts in the cause of medical education and of medical reform have done much to elevate the status and honour of the profession in this country, but cannot be more than noticed here. He was possessed of high intellectual acquirements, artistic taste, and literary attainments; witness his *Life of Petrie*, his most intimate friend, published in 1868. His social qualities were of the most genial and agreeable nature; his benevolence was unbounded, and his kindness of heart and disposition endeared him to all with whom he came in contact.

Stokes was the recipient of many professional and scientific honours. In 1830, the University of Dublin conferred on him, *honoris causa*, the degree of M.D.; and in the same year he was elected a Fellow of the King and Queen's College of Physicians in Ireland. On three separate occasions, he was chosen President of this ancient corporation; and, while their President, was also the President of the British Medical Association during the year of its memorable meeting in Dublin in 1867. On his father's resignation of office in 1845, Dr. Stokes succeeded him as Regius Professor of Physic in the University of Dublin, and filled this high position with dignity and usefulness up to the time of his death. The Universities of London and Cambridge both conferred on him their degree of LL.D., and the University of Oxford that of D.C.L. He was a Fellow of the Royal Society, and in 1874 was elected President of the Royal Irish Academy.

On the formation of the General Medical Council in 1858, he was nomi-

nated by the Crown as its Irish representative member, an office which he only resigned, in consequence of his impaired health, last May. Dr. Stokes was also Physician in Ordinary to the Queen in Ireland, and Consulting Physician to several medical institutions. The last honour he received was probably the more highly valued because unexpected. It was the presentation, through the German ambassador from his Emperor, of the insignia of the Prussian order "Pour la Mérite", to which Stokes was nominated in 1875, along with such other distinguished men as Longfellow, George Bancroft, and Schwann. His numerous friends and admirers also honoured him during his life by the erection of his statue, by Foley, in the hall of the King and Queen's College of Physicians.

Stokes did not obtain any title. He never coveted any; he never sought any. He was a prince from birth of the aristocracy of intellect. His name is crowned with the triple coronet of the gratitude of the poor, for whom he tenderly and piously cared; the confidence of the public, whose approbation he universally secured; and the love and esteem of his profession, whose honour and interests he unflinchingly upheld.

#### BRITISH MEDICAL ASSOCIATION MEDAL.

THE Association medals, established by vote at the last annual meeting, in virtue of a resolution of the Committee of Council moved by Dr. Sieveking and Mr. Callender, and warmly supported by Dr. De Bartolomé of Sheffield, the President of the Association during the year 1876-77, were on Wednesday handed to the recipients, whose names were then announced, and who had so greatly distinguished themselves by their devotion to duty, under circumstances of no small peril and hardship, on the occasion of the inundation in the mines at Pontypridd. We had the advantage of publishing, from the pen of Mr. H. Naunton Davies, who directed the medical staff, in the JOURNAL of May 12th, a simple and modest recital of the circumstances, which deeply interested the profession, and has left an enduring memory of the courage and noble conduct of himself and his medical companions. The Albert Medal was granted to most of the leaders of this heroic enterprise, but, strangely enough, was withheld from all the medical men concerned. In instituting this special medal of merit, the British Medical Association has expressed its sense of the high claims to gratitude of those gentlemen, and has at the same time established a precedent for the recognition of high merit of the kind, which will have an enduring, and it may be hoped an increasing, value. In thus repairing an omission which it is impossible not to feel, the Association will have made a silent but practical comment on the neglect which it is too often the custom to show towards medical deeds of heroism, while those achieved by other callings are profusely rewarded with public honour. The medals were presented at a dinner given by the Committee of Council, with appropriate addresses by Dr. Wilkinson, the President of the Association, and Dr. Falconer, President of Council; and were acknowledged by the recipients in interesting speeches, of which we hope to be able to present a report.

#### THE NEW NORTH OF IRELAND BRANCH.

WE learn with great pleasure from Dr. John Moore of Belfast, that the meeting on the 3rd instant for establishing the North of Ireland Branch of the British Medical Association was most successful, and that the Branch was formed under the most favourable auspices and with warm support. The meeting was held in the Lombard Hall, Belfast, Dr. J. K. Maconchy, of the Downpatrick Infirmary, in the chair. A suitable series of by-laws was submitted and passed. Ten members of the profession were elected members of the Association and Branch, and forty-two existing members of the Association joined the Branch. It thus opens with fifty-two members, and others whose applications were received too late are waiting election at the next meeting of the Council. The following officers were appointed for the ensuing year. *President*: James Cuming, M.D., Belfast. *Vice-Presidents*: J. K. Maconchy, M.B., Downpatrick; J. W. T. Smith, M.D., Belfast. *Council*: W. Arnold, L.K.Q.C.P.; F. E. Beck, M.R.C.P.Ed.; J. W. Browne, M.D., Belfast; A. Dunlop, M.D., Holywood; J. Fagan, L.K.Q.C.P., Belfast; H. Frazer, L.K.Q.C.P., Armagh; G. Gray,

M.D., Castlewells; R. Gray, L.K.Q.C.P., Armagh; A. Harkin, M.D., Belfast; A. Kidd, L.K.Q.C.P., Ballymenor; W. A. McKeown, M.D., Belfast; Sir William Miller, M.B., Londonderry; C. D. Purdon, M.B., Belfast; E. Thompson, M.B., Omagh; G. F. Wales, M.D., Belfast. *Secretary and Treasurer*: John Moore, M.D., Belfast. The names of these gentlemen will command the esteem and confidence of the profession in the north of Ireland, and no doubt the numbers of the new Branch will soon be largely increased.

#### THE PATHOLOGICAL SOCIETY OF LONDON.

THE annual meeting of this Society was held on January 4th, when the report of the Council was read by the Surgical Secretary. It stated that the number of members was now six hundred and one, of whom thirty-two had joined during the past year. Five members had died in 1877, viz., Sir William Fergusson, Dr. Snow Beck, Mr. William Coulson, Dr. Basham, and Mr. William Carr; and eight members had retired. The success attending the setting apart of certain meetings for the discussion of special pathological questions, as that of visceral syphilis, which had been discussed in 1877, was so great that the Council had determined to continue the plan; and the subject chosen for the coming year was that of Diseases of the Lymphatic System, including Lymphadenoma and Leukæmia. The new volume of *Transactions* was also enriched by the communications of Sir W. Gull and Dr. Sutton on Arterio-capillary Fibrosis; of Dr. George Johnson on the Changes in the Blood-Vessels in the Small Red Granular Kidney; of Mr. Godlee on the Organisms characteristic of Vaccinia; of Dr. Braidwood and Mr. Vacher on Vaccinia and Variola; of Dr. Klein on Scarlatina and on Pig-Typhoid; and of Dr. Gowers on Hydrophobia. A committee was appointed to inquire into the infective processes known as Pyæmia, Septicæmia, and allied diseases, and included representatives of each of the large Metropolitan hospitals; of these, a working committee was selected, consisting of Mr. Marcus Beck, Dr. Greenfield, Mr. McCarthy, and Dr. Ralfe. Application was made to the Local Government Board for assistance in an inquiry which might be very important to the welfare of the public. A grant of £350 was at once made, and the Committee had since been actively engaged in pursuing its investigations. A Committee had also been formed to inquire into the structure of the arteries and capillaries in Bright's disease with contracted kidney. As it was composed of Dr. Burdon Sanderson, Dr. Bristowe, Dr. Gowers, Dr. Charles, and Mr. Schäfer, the Council looked forward to a report of considerable value. The Morbid Growths Committee had revised its rules, which were printed in the volume of *Transactions* for 1877. The expense of the *Transactions* had been very large; but the valuable engravings attached to the paper of Sir W. Gull and Dr. Sutton had nearly all been liberally contributed by the authors. The Treasurer's balance-sheet showed a sum of £1,067 15s. 1d. invested in the names of the Trustees, and of £15 17s. 4d. in hand. The greater part of the annual expenditure was for the volume of *Transactions*.

Mr. Wood moved, and Mr. Howse seconded the proposition, that the report be adopted. The motion was carried unanimously. Dr. Tatham proposed a vote of thanks to the retiring officers, which was acknowledged by Dr. Hare. Dr. Hare then in highly eulogistic terms proposed a vote of thanks to the retiring secretary, Mr. Wagstaffe, upon whom the chief work of the Society during the past year had fallen. The proposition was seconded by Mr. J. Wood, and carried with enthusiasm. Mr. Wagstaffe acknowledged the vote.

Dr. Goodhart and Dr. Dowse, being appointed scrutineers of the ballot-box, reported that the officers nominated by the Council had been elected. These were as follows. *President*: Charles Marchison, M.D., L.L.D., F.R.S. *Vice-Presidents*: Edward Headlam Greenhow, M.D., F.R.S.; \*George Harley, M.D., F.R.S.; Walter Moxon, M.D.; \*Hermann Weber, M.D.; Thomas Bryant, Esq.; George W. Callender, F.R.S.; \*Thomas William Nuin, Esq.; Thomas Smith, Esq. *Treasurer*: John Whitaker Hulke, F.R.S. *Honorary Secretaries*: R. Douglas Powell, M.D.; \*W. Morrant Baker, Esq. *Council*: William Cayley, M.D.; \*Sidney Coupland, M.D.; James Frederick Goodhart, M.D.; \*William Richard Gowers, M.D.; T. Henry Green, M.D.; William Smith Greenfield, M.D.; Charles Henry Ralfe, M.D.; John Charles Thorowgood, M.D.; Charles Theodore Williams, M.D.; \*John Williams, M.D.; William Adams, Esq.; Edward Bellamy, Esq.; Henry Trentham Butlin, Esq.; Rickman John Godlee, Esq.; \*Henry Greenway Howse, Esq.; \*Jeremiah McCarthy, Esq.; \*William Mac Cormac, Esq.; Henry Morris, Esq.; Arthur Treherne Norton, Esq.; \*William Warwick Wagstaffe, Esq. The gentlemen whose names are marked with an asterisk (\*) were not on the Council or did not hold the same office during the preceding year.

## HYDROPHOBIA AND RABIES.

THE Committee recently appointed by the Scientific Grants Committee of the British Medical Association "to organise an inquiry into the Causation, Pathology, and Treatment of Rabies and Hydrophobia", consisting of Mr. Callender, F.R.S., Dr. Burdon Sanderson, F.R.S., Dr. T. Lauder Brunton, F.R.S., Mr. Ernest Hart, and Dr. Gowers, desire to announce that they will feel favoured if any medical gentleman having under his care a case of hydrophobia will kindly communicate with them. In any cases of hydrophobia or of rabies in which a *post mortem* examination is made, they will be glad to receive for investigation the following parts; namely, the spinal cord, medulla oblongata and pons Varolii, a small piece of the cerebellum, corpus striatum, convolutions of the middle third of the brain, one of the salivary glands, the nerves leading to the part bitten, portion of the liver and of the kidneys, and the scar. These should be at once placed in a mixture of equal parts of spirit and water (or, if the organs be at all softened by commencing decomposition, in a mixture of three parts of spirit to two parts of water), and forwarded with as little delay as possible, together with a report of the *post mortem* appearances, to the Office of the British Medical Association, 36, Great Queen Street, London, W.C.

The members of the Committee are also anxious to have the opportunity of visiting cases of hydrophobia under treatment, or of attending any *post mortem* examinations in fatal cases.

At a recent meeting of the magistrates of the county of Cornwall, the chief constable called the attention of the Court to the spread of hydrophobia in this county. Notwithstanding that every precaution has been taken in the districts where it exists to prevent it, he regretted to have to report that one child had died from it, and two other persons had been bitten by a mad dog. One horse, two head of cattle, fifty sheep, seven pigs, five cats, and fifty-three dogs had been killed or died of the disease, and he feared there were still many animals alive in the county that had been bitten by mad dogs. Colonel Tremane desired to obtain some information with reference to the number of unlicensed dogs in the county. He knew there were a great many, but he did not hear of very many prosecutions, and he could not help thinking that if the law were altered, and the police had the power to prosecute, the dog nuisance would be greatly abated. The chief constable replied that the police could only report to the Excise, as they had done in a great number of cases; within the last month, no less than sixty-one such cases were reported at Liskeard alone. Many cases were dropped, and he knew that many were compromised, while others came before the magistrates; but whether they were all reported at Somerset House or not, it was quite impossible for him to say. A motion was passed to the effect that the attention of the authorities at Somerset House should be called to the fact of so many reports having been made without being followed by prosecutions.

An inquest was lately held at Wycombe Marsh, High Wycombe, on the body of a child named F. E. Rumbelow, aged 7. The deceased was bitten by a black and tan terrier dog, and some days later was taken ill at school. A wound on her leg, caused by the bite, was very much inflamed, and her mother applied cold water bandages. On the following morning, the child said the wound was not so painful, but complained of soreness in the throat. She gradually got worse from that time, and died displaying all the symptoms of hydrophobia. The deputy-coroner (Mr. G. A. Charsley) hoped the Chancellor of the Exchequer would take some restrictive steps regarding dogs during next session.

## HOSPITAL AND DISPENSARY MANAGEMENT.

## THE PLYMOUTH FREE AND PROVIDENT DISPENSARIES.

MR. W. H. ALGER has forwarded to us a copy of a pamphlet on the *Outline of a Scheme for the Amalgamation of the Plymouth Public and Provident Dispensaries*. The Court of the Governors of the Public Dispensary have resolved that "this Court gives power to its Committee to adopt the provident system in connection with this institution". Mr. Alger proposes that effect should be given to this resolution in the following manner. In future, a subscription of one guinea to the Public Dispensary should entitle the subscriber to four recommendation papers. These recommendation papers should be given to applicants for medical advice, not as a title to gratuitous treatment, but, as it were, as payment on their behalf of the sick fines, which—not having previously become members of the provident dispensary—

they would, according to the usual rules of a provident dispensary, be required to pay on admission to its benefits during illness. The subscriber would thus have in his hands the power of absolving from the sick fine those to whom he gave his paper of recommendation. After being admitted in this way, the patient would take his place as an ordinary provident dispensary member, and would pay sixpence, which would thus be considered equivalent to the weekly payment of an ordinary member for six weeks. After six weeks, the patient would be induced, if possible, to continue his weekly or monthly prepayment, and he would not be allowed to have the benefit of medical attendance on any other footing for another six weeks, unless it were found on inquiry that he was a suitable recipient for further gratuitous advice. Mr. Alger points out that "in this way, whilst the provident system would be engrafted upon the Public Dispensary, yet the charity would still be holding out a welcome hand to those poor persons who could not afford to pay for medical assistance; and the investigations which would be made into the merits of each case, whilst weeding out improper persons, would doubtless bring into notice the really necessitous cases, and thus enable the benevolent to render aid to them in other ways". The scheme is a good one, and we shall be glad to hear that it has been adopted.

## ASSOCIATION INTELLIGENCE.

## BATH AND BRISTOL BRANCH.

THE third ordinary meeting of the Branch will be held at the York House, Bath, on Wednesday evening, January 30th, at a quarter past Seven o'clock: H. MARSHALL, M.D., President.

The evening will be devoted to the discussion of Hospitalism, which will be opened by R. W. Tibbitts, M.B.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, December 31st, 1877.

## DUBLIN BRANCH.

THE first annual meeting of this Branch will be held in the Hall of the King and Queen's College of Physicians, Kildare Street, on Wednesday, January 30th, at 4 P.M. The President, Dr. HUDSON, will deliver an address.

The annual dinner of the Branch will also take place at 7 P.M. the same evening in the College.

GEORGE F. DUFFEY, M.D., *Honorary Secretary.*

30, Fitzwilliam Place, Dublin, January 5th, 1878.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH:  
ORDINARY MEETING.

THE third ordinary meeting of the session 1877-8 was held in the Queen's College, Birmingham, on December 13th: present, Mr. SAMPSON GAMGEE, President, in the Chair, and thirty-six members.

*New Members.*—The following members of the Association were elected members of the Branch: Mr. Bradford, Smethwick; Mr. Farncombe, Mr. Hex, Mr. S. F. Palmer, Mr. Suffield, Mr. H. W. Thomas, and Dr. Vinrace, of Birmingham.

*Communications.*—The following communications were made.

1. Dr. B. Foster: Obstructive Jaundice and Cancer of Liver.

2. Mr. Lawson Tait: Myxoma Uteri.

3. Dr. Saundby: Intestinal Pathology.

4. Mr. H. L. Browne read a paper on Stricture of the Urethra, showed some new instruments for the treatment of urethral stricture, and exhibited a patient upon whom he had successfully performed the operation of perineal section.

6. Mr. Bartleet read a paper entitled Notes on the Treatment of Wounds. A discussion followed, in which Mr. Gamgee, Dr. Monckton, Mr. Yates, Mr. J. H. Palmer, Mr. H. L. Browne, Mr. J. F. West, and Dr. Taylor shared.

*The Annual Meetings of the Association.*—Mr. MORGAN (Lichfield) moved: "That it is desirable that a Local Reception Committee be formed in the town where each annual meeting of the Association is to be held, so as to provide, as far as possible, private hospitality for the members." Dr. MONCKTON (Rugby) seconded the motion. After remarks from Dr. Foster, Mr. Watkin Williams, and the President (who suggested that the question be brought before the Committee of Council of the Association by the senior Secretary), Mr. Morgan withdrew his motion.

## CORRESPONDENCE.

## THE LOST SCHOOL.

SIR,—The letter of your correspondent, "A Member of Convocation", invites this further information in reference to the Chair of Clinical Medicine.

The professorship was founded under the will of Lord Lichfield in 1772. The professor is elected by the Convocation of the University. His duties are to visit the patients in the Radcliffe Infirmary daily from November to March, and to read a lecture two days a week. If the professor neglect his attendance, a year's stipend is forfeited to the Infirmary, and £5 is forfeited for each lecture omitted. It does not appear, from the annual reports of the Infirmary, that any forfeits have been received.

The endowment produces £200 a year, and is in the hands of the trustees under Lord Lichfield's will; the Chancellor of the University, the Bishop of the Diocese, and the President of St. John's College.

An application to the Charity Commissioners might perhaps have the effect of hindering the fund from being diverted from the purpose intended by the founder, that of educating pupils for the medical profession.—I am, sir, etc.,  
CIVIS.

Oxford, January 8th, 1878.

SIR,—The recovery of the lost medical school at Oxford is a fair subject for suggestion and discussion; its speedy consummation we most devoutly desire; but we regret that its consideration should have been made by "A Member of Convocation" an excuse for a tirade against Drs. Acland and Rolleston. We are not concerned to defend sinecures anywhere, however blameless their holders may be; we respect and admire Dr. Acland, and wish we could gainsay the comments of your correspondent upon the false position occupied by him at Oxford. We can only reprobate the adoption of so harsh a tone towards the man to whom is due the chief credit of the new museum at Oxford. Of Professor Rolleston we will say, that his methods are and have been so far in advance of biological teaching elsewhere, that they are now being generally adopted wherever in England biology is taught; that the results of his teaching are excellent; and that to him the University is indebted for much of the impulse that has lately been given to scientific study at Oxford. In the catholicity of his interests, combined with earnestness of purpose and vigour of intellect, he is a shining example to those men of science whose narrow sympathies and lack of literary and general culture have made the name of science stink in the nostrils of many educated people, and have produced a reaction that may be felt from the once popular cry for scientific education. No one conversant with the real state of things can for one moment suppose that the decay of the medical school at Oxford is due to any faults of omission or commission by the professors of Medicine and Anatomy. The causes lie much deeper, and can only be met by measures much more stringent and searching than decrees of Convocation to enforce regular lectures on Medicine and Human Anatomy to empty benches.

There are really two distinct grievances mixed up, and to a certain degree confused, in the letter of last week. The first is that Oxford is not, like Cambridge, the seat of a local or provincial medical school. The second is that so few medical degrees are conferred at Oxford, that the University may virtually be said to do nothing for the education of the medical profession throughout the country.

With regard to the first, those disadvantages which attend all provincial schools would also attend a school at Oxford. The chief of these are a dearth of distinguished teachers, and an alleged absence or insufficient supply of good medical and surgical cases for clinical teaching. There can be no question of the vast superiority of the metropolitan schools in these respects; and it is to an appreciation of this superiority, and not to a contempt for medical studies, as illiberal and empirical, that we must attribute the discouragement offered by the Medical Faculty to the resuscitation of a school at Oxford. We think, however, that this is but a partial statement of the merits and demerits

of such a design. The first two years of a medical student's course are for the most part spent in the study of the scientific basis of medicine and surgery. For this study, Oxford, unlike most provincial towns, offers advantages unequalled, except perhaps at Cambridge. It has museums, dissecting-rooms, laboratories, and a staff of teachers, which in eminence is superior, we venture to think, to that of any other educational body in the kingdom. Nor need hospital work be neglected. At Oxford, as at Cambridge, there are opportunities for clinical work amply sufficient for a student during his first two, if not three, years, when he might prepare himself for the more advanced teaching of the London schools. Six hundred beds are not a necessary condition of good clinical teaching; witness the small but famous hospitals crowded by the genius for teaching of Graves, Niemeyer, Todd, Liston, Jenner, Lister, and Ringer. Good teachers make good cases, and are not made by them, and such teachers ought to be found in Oxford, which claims to be the head-quarters of teaching and learning.

The foundation of a medical school at Oxford will not be enough to attract thither any considerable number of students. Something must be done to reduce the amount of time and money necessary to the attainment of a degree. Let there be but a strong and persistent demand from outside for economy in Oxford, and a supply of that very scarce article will, no doubt, be forthcoming. The success which has attended the institution of unattached students, and the foundation of Keble College, are signs of the times. A more serious obstacle to the success of a medical school lies in the inordinate length of the medical course. A student cannot take a degree in medicine in less than seven years from the date of his matriculation; as a matter of fact, few degrees are taken in less than nine. This protracted course is due to the fact that the University requires a degree in arts to be taken before the commencement of professional studies, basing its regulation upon the theory that a degree in medicine ought to presuppose a liberal education. This is an excellent theory, worthy of respect and imitation elsewhere; but, in its present application, it assumes that medical studies in themselves are incapable of affording a liberal education. It is perhaps true that there is an absence of wider interests, of even a faint tinge of literary culture and of intelligence in its larger sense, among the medical students; that, in most class-rooms, they are taught to observe and remember, but not to think, save superficially. This is a state of things separable from the subject-matter of their education, but inseparable from its present methods. Professional education invariably tends to degenerate into a mere process of information where it is divorced from the more critical spirit and humaner aims of general education. This is the position of the English medical schools, in which they neither influence nor are influenced by those waves of thought which move all other centres of education. All this would be changed by the establishment of a closer connection between them and the English universities. The gain would be a mutual one: Oxford, at any rate, would be all the better for contact with the practical spirit of medicine and surgery. The advantage to medical students of University life, and with it of more refined habits of thought and action, would raise the status and tone of the whole profession. It is its intimate relation with the Universities that in part gives the clerical profession an influence and superiority over our own profession, not social only, but also moral, intellectual, and literary, in spite of the fact that doctors, as a body, are professionally far more learned than clergymen. But the University must acknowledge the dignity of medicine; it must recognise its capability of being made the subject of a liberal education; it must cheerfully accept the position of its teacher, Herbert Spencer, that that education is best which can be made at once a means of cultivation and a source of utility to the individual and the state.

This is not the place to enter upon details; but we appeal to Oxford graduates to meet and consult about the best means of re-establishing a medical school, and to consider, amongst others, the questions of College and University expenses, of an increase in the number of science scholarships and medical Fellowships, of shortening the academical course for a medical degree by a recognition of time spent in medical studies at the University, of lengthening the duration of term-time, which now only lasts six months. In this last point, we see a possible stumbling-block and rock of offence to the University professors; but term-time has been lengthened at Cambridge, and why not at Oxford? The University has relaxed the rigidity of its regulations in favour of selected candidates for the Civil Service of India; why should it not do so for medical and law students? It wants but a Professor Humphry at Oxford, and a medical education there would be a reality, instead of being what it is now, a scandal and disgrace to the University by its absence.—Your obedient servants,

TWO OXFORD GRADUATES IN MEDICINE.

## PHYSICIANS' FEES.

SIR,—Having read a letter in the BRITISH MEDICAL JOURNAL of December 22nd, 1877, headed "Physicians' Fees", I beg to offer a few remarks on the subject. I think all will agree with F.R.C.P. that some reform is necessary, and that the question is one of interest both to the members of the profession and to their patients. What appears to me to be required is a thorough and proper understanding between the consultant, the general practitioner, and the public. The public cannot be expected to understand in detail medical ethics; and I fear (judging from the numerous letters in the professional journals) that many of our body are not so well informed in matters of etiquette as they ought to be. We must first ourselves understand before we can hope to teach others. During a period of many years' practice in a suburban district, I have been brought into contact with a large number of persons of different classes, and have generally found my patients anxious "to do what is right", but not always clear in their notions; let, then, the medical man help his patients in these matters. Another point: many practitioners resent the proposal for a consultation, thus driving their patients to seek other advice on the sly; surely this is neither wise on the doctor's part nor fair to the general body of consultants. If the general practitioner understand his case, a consultation can only strengthen his hand; and, if he be in any doubt, he should, in common justice to his patient, seek counsel. Next, as to the consultant; why should he not ask his patient if she or he be under treatment, and, if the reply be in the affirmative, decline to see her or him except in consultation? When the consultant is called to a distance, it must nearly always be in consultation, and, in these cases, the family attendant should take care that the physician receives his proper fee. In cases where the physician visits his patient "by himself" and allows his visits to "run on", I am inclined to think it is frequently his own fault if he lose his fees, as many of these cases would fall more legitimately to the general practitioner, who has the advantage of being able to sue his dishonest patients.—I am, sir, your obedient servant,  
GENERAL PRACTITIONER.  
London, S.E., December 24th, 1877.

SIR,—Your correspondent F.R.C.P. seems sadly aggrieved at the low remuneration he receives for what is called a "consultation". But does it never strike him that the trouble of undressing and of using the stethoscope, thermometer, and test-tube is less needed there than on other occasions? The general practitioner accompanying the patient (if an enlightened and intelligent man) has almost invariably done all this work beforehand, and put the physician in possession of every symptom of the case, thus rendering the task of the latter so far easier, that he has little left to do, except to confirm or corroborate all that he has been told; and, moreover, is spared the trouble of asking the patient more questions than are absolutely needed.

Why, therefore, a double fee should be demanded in such cases, and why such an abuse as that of "consulting fees" was ever instituted, I am utterly at a loss to conceive. Doubtless it is the main cause of widening the gap between physician and general practitioner, and of rendering the latter shy of consulting the former, especially with patients from the country.

The complaints of being mulcted of a shilling out of a guinea, or of receiving ten for twelve guineas, must sink into mere insignificance, if F.R.C.P. considered that his hard working brother the general practitioner has to pay visits at five shillings, three and sixpence, and, to the poorer classes, as low as half-a-crown, and suffers losses by bad debts, which may be reckoned, not by units only, but by tens and often by hundreds.

Trusting these remarks may find a place in your valuable columns, I beg to remain, sir, your obedient servant,

A GENERAL PRACTITIONER.

SIR,—Permit me to offer a few remarks in reply to the grievances complained of by F.R.C.P. This I venture to do, after more than a quarter of a century's experience, the greater part of which was occupied in an extensive London practice.

It is one of the distinguishing features in the etiquette of a consultant that he receives his fee at the time. This is his only means of securing payment, since it is admitted that the public are both "thoughtless and selfish"; besides, it is but fair to the general practitioner that it should be so. My invariable custom has been to secure the fee and hand it over after the consultation. This plan prevents confusion, and gives satisfaction to both consultant and patient. Where there is no consultation, the fee should be regarded as a professional matter of business. The system of which F.R.C.P. speaks, to allow his visits "to

run on", is, to my mind, very objectionable and unfair to the general practitioner; and so is the anomalous practice of taking alternate fees. Discard this system, which is too prevalent, and more intimacy would arise between consultant and non-consultant. This, I think, should be encouraged, since it is productive of good to the patient and is not detrimental to both classes of medical men. The knowledge of these facts may not come before the ordinary practitioner so much as those who conduct a special practice, and who see a large number of patients who have gone the rounds of our leading consultants. Allow me to say a word as to fees. No fee should be under a guinea, except in special cases, and with the family medical attendant, two guineas and upwards.

I am, etc.,

ROBERT CUFFE, Surgeon.

The Villa, Woodhall Spa, January, 1878.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 8TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

## ON THE MICROSCOPIC ANATOMY OF CHRONIC INFLAMMATION OF THE SURFACE OF THE TONGUE.

BY HENRY T. BUTLIN, F.R.C.S.

THE object of the author was to give an account of the minute anatomy, hitherto undescribed, of the smooth glossy tongue, called by Dr. Fairlie Clarke "chronic superficial glossitis". The paper was based on the examination of the tongue in three cases in the practice of Sir James Paget, Mr. Thomas Smith, and Mr. Langton. The characters of the disease were described as consisting of thinning of the epidermis, an destruction of the papillae and other appendages; and of thickening an increased vascularity of the corium and submucous tissue, and infiltration with small cells. A comparison was drawn between the characters of this disease and psoriasis or ichthyosis of the tongue. There was apparently no essential difference in the microscopical characters of the two diseases. (The paper was illustrated by drawings.)

Mr. GASKOIN had lately seen a case of lupus affecting the left side of the nose, accompanied with a smooth patch on the same side of the tongue, which appeared to increase in extent *pari passu* with the destruction of the ala nasi.—Dr. THIN thought that the drawings well represented the earlier stages of epithelioma of the tongue. The smooth tongue met with in dysentery much resembled this condition microscopically.—Sir JOSEPH FAYRER referred to the smooth glazed tongue met with in the chronic or hill diarrhoea of India, and indicative of an advanced stage of the disease. The normal condition was sometimes regained; but it was always of serious import.—THE PRESIDENT asked whether the smooth tongue described by Mr. Butlin was to be regarded as a local disease. In the dyspepsia and intestinal diseases of children, the tongue sometimes presented smooth patches. This condition was seldom seen after the age of twelve or fourteen; and it appeared to be connected with the second dentition.—Mr. BUTLIN had never seen a case in which lupus and the smooth tongue occurred together. He had seen a case of smooth tongue in a case of chronic diarrhoea in a woman; but it appeared as if the horny layers had disappeared. The smooth tongue in children was probably of the same character as that met with in diarrhoea and dysentery. He thought that the condition described in his paper was local; the patients had the affection a long time without presenting constitutional symptoms.

## MATERNAL IMPRESSIONS. BY WILLIAM SEDGWICK, M.R.C.S.

MR. SEDGWICK said that great care had been taken to avoid, as far as possible, any unnecessary reference to cases which possessed no practical significance, or which, from their doubtful character, would tend to increase scepticism. In reproductive development, women, as a rule, transmitted with more facility than men. The normal influence of the mother on the intellectual development of her offspring had been well and familiarly expressed in the term "mother-wit"; and, in abnormal development, it had been long known that women often served, and to a far greater extent than men, as conductors of an inheritance which they did not share. In like manner, it was now popularly believed that it was the emotional impressions of the mother, and not those of the father, which were imparted to the fetus in the form of "mother's marks". But this assumed limitation of emotional impressions to one sex did not always prevail; for originally either parent

was thought to be capable of imaginatively affecting the offspring at the period of conception, and traces of this form of the belief had been lately found among some of the tribes in Central Africa. There was an essential difference between cases in which some modification of foetal structure had been slowly effected through the influence of the perceptive faculties, and those cases in which emotional impressions had been believed to act on the foetus by causing a supposed sudden arrest in its development. The occasional transmission to offspring of acquired defects of structure could not be logically objected to, since all abnormal modifications of the system must have been acquired before they could have been transmitted. It was no doubt difficult to distinguish between the alleged influence of maternal impressions and that of heredity. The establishment, through hereditary influence, of acquired instincts in the lower animals, as well as the occurrence of hereditary talent in our own race, was apparently due to some modification of structure: and when, in like manner, maternal impressions had been said to react specially, if not exclusively, on the nervous system of the offspring, the effect might, with equal probability, be referred to some modification of structure produced through the medium of the blood. The exaggerated importance which had been assigned to nerve-communication, as the only probable way by which the supposed influence of maternal impressions could be conveyed to the foetus, had no doubt had a tendency, in former years, to retard and obscure the inquiry; and the opinion was expressed that the limitation of the influence of a maternal impression to a corresponding organ or tissue in the foetus, as a consequence of some slight and inappreciable alteration in the blood of the mother being imparted to the local nutrition of her offspring, might physiologically be regarded as more probable than limitation effected by nerve-influence. There was no reliable evidence that a congenital defect had ever been the direct and immediate result of arrested development; whilst the popular belief that a maternal impression could be conveyed to the foetus, and affect it like an electric shock, should be simply dismissed as a popular fallacy. The influence of the impression, at an early period of pregnancy, could only be conveyed to the part through the medium of the blood, or nutrient fluid. Mr. Sedgwick directed attention to the comparative physiology of reproduction in the lower animals; and showed that, when the tendency to an artificially developed excess of structure had, through hereditary influence, been pushed too far, it was apt to be followed by deficiency and arrest, as in the case of some top-knotted varieties of birds. Abnormal increase of structure, without any subsequent arrest, occurred in cases of supernumerary fingers and toes, which had been sometimes referred to the influence of maternal impressions; and there was local increase of the vascular tissue in naevi, and of the hair, if not always of the skin, in those pseudo-mimetic moles which had been said to resemble the rats, mice, and other animals with hairy skins, which had frightened women during pregnancy. It might be expected that a maternal impression, sufficient to produce a physical peculiarity or defect in the foetus through the medium of the blood, would reappear, at least in a modified form, in some of the succeeding offspring; but there was very little evidence of any kind in favour of such an occurrence. Referring to the episode of Jacob's rods, he said that they were apparently employed, not to originate, but simply to aid in the increased production of specially marked offspring. There had been many illustrations of the effect produced by variously coloured objects, on the breeding of sheep and other animals, since patriarchal times. Dr. Alexander Harvey and other observers had collected and published evidence on the subject. The evidence in favour of the influence of maternal impressions did not appear at present either sufficiently relevant or trustworthy.

Mr. DONALD NAPIER showed casts from the mouth of a lady aged 25 or 26, in whom the milk-teeth were still present, none having been shed except two upper incisors. Other members of the family had the same peculiarity. He would not attempt to determine how far in the present case the condition was due to hereditary influence or to a dread of its occurrence on the part of the mother.—Mr. SAVORY said that diseases might be transmitted from the mother to the foetus; but it was more difficult to conceive how an impression on the mind of the mother could produce a corresponding physical defect in the foetus.—Dr. THIN would like to have the alleged cases of maternal impression put to a test. General impressions in such matters were of very little scientific value.—Dr. MATTHEWS DUNCAN said that the subject of maternal impressions was now and then brought before medical societies; but no progress would be made in it until coincidences could be distinguished from consequences.

*Favus*.—Mr. GASKOIN showed a case of favus in a boy, the child of Polish parents. The disease appeared to be of rare occurrence in London.

## PATHOLOGICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 4TH, 1878.

CHARLES MURCHISON, M.D., LL.D., F.R.S., President, in the Chair.

*Bromide of Potassium Eruption*.—Dr. CROCKER brought forward a patient presenting an eruption due to the administration of bromide of potassium. An infant, aged eight months, was sent to the Skin Department of University College Hospital on December 22nd for diagnosis. The father died of consumption some months before its birth; the mother was healthy; and the child was well up to the time of vaccination. It was vaccinated in August last, and about the twelfth day a rash appeared all over the body, which, according to the mother's description, consisted of small red spots of the size of a millet-seed, raised above the surface, with whitish watery heads. This died away in a few days, but fresh crops appeared from time to time for about three weeks. After this, the skin remained clear until the present eruption. The child was not, however, quite well; and, after vomiting on November 12th, had convulsions, which continued at intervals until the 19th, and for which one grain of bromide of potassium three times a-day was prescribed, beginning on the 12th, and continuing until the 24th, when the dose was increased to two grains three times a-day, which was taken up to December 13th. From November 19th to 24th, a quarter of a grain of iodide of potassium was given with each dose of bromide. The eruption appeared at the beginning of December on the site of the vaccination, and the medical man attending it described it as, at first sight, like a vaccine vesicle of about the tenth day. When brought to the hospital, the child presented the following appearances. On the site of the vaccination, there was an irregular patch, of the size of a crown-piece, covered with a thick, raised, sienna-coloured scab, irregularly sulcated and split up; on the border were two small pustules, but no surrounding inflammation. On the face there was a patch of the size of a shilling on each cheek; but they had been rubbed, and were discharging. On the buttock and loins were several patches, and some of them showed a central scab on an oval base of the size of a horse-bean. This base was raised about one-sixteenth of an inch above the surrounding skin, was pale red, and appeared to be made up of new tissue. At the end of December, a fresh crop appeared on the arms and face, and then it could be seen (as in a similar case exhibited last year to the Society by Dr. Lees, and published in the current volume of *Transactions*) to commence as a red papule, which soon became an acuminate pustule on a raised, soft, red base, and appeared to be due to an inflammation of the follicles. These pustules were aggregated into patches of variable size, from half-an-inch to two inches in diameter, increasing by the addition of pustules to the circumference; but, as Dr. Lees had observed, as long as the pus remained, the heads of the individual pustules could be discerned. Solitary papules and pustules were also to be seen on the arm and face, and in these the acneiform character of the eruption was apparent; but the abundant cell-formation gave a more pustular condition than is seen in ordinary acne. Subsequently thick crusts (as described above) were formed; but between these two stages was another, when the fleshy-looking tubercles alluded to before were present. There were, therefore, three stages in the eruption: 1. A pustule, or aggregation of pustules, on a soft, raised, and reddened base; 2. Pale-red fleshy-looking tubercles, either round or oval, in size varying from a pea to a bean; 3. Thick dark crusts, tuberculated and split up by deep sulci. The face, arms, loins, and buttocks, but especially the first two, were the parts chiefly affected in this case, which differed thus from that of Dr. Lees, in which the limbs and back were but slightly affected. The fact that the eruption first appeared on the site of the vaccination, and the small dose of the bromide, were points worthy of note.

Dr. BARLOW had seen cases exactly similar to the present, in which bromide of potassium alone had been given. It was an interesting point that the eruption commenced in an old vaccination-mark. He had observed the same in a case of his own, where the eruption first made its appearance on the site of an unhealed blister. This bromide eruption appeared when very small doses of bromide of potassium were given. He thought there was unquestionably a connection between the common acneiform eruption of bromism and the present form, inasmuch as all degrees of variety could be traced between them. Idiosyncrasy played an important part in the development of this extreme form.—The PRESIDENT asked whether the present form of eruption was considered equally common in the adult. He had not himself seen anything approaching to this in the adult. Quite lately, he had seen a young lady who had taken a drachm of bromide of potassium daily for eight years; but she did not suffer from any eruption. So rare were cases like the present, that he questioned whether they were not due to some other cause.—Dr. HARE said that he had never met with the

eruption. If it were a variety of the acne due to bromide, it might be expected to appear at puberty, and yet it did not.—Dr. FREDERICK TAYLOR said that it must not be supposed, from the remarks that had been made, that bromide eruptions were common in children. They certainly were rare.—Dr. CROCKER replied that he had never before seen an eruption like the present, either in the adult or in the child. Its form was, perhaps, due to the greater tendency to pus-formation in the child. With respect to bromide eruptions generally, he had ascertained that even the ordinary acne was exceptional among patients taking the drug at the Epileptic Hospital.

*General Hyperostosis, with Osteo-Arthritis of Several Joints.*—Mr. HOWSE exhibited a man suffering from these diseases. The patient, aged 37, had been a soldier, who sixteen years ago had received a kick in the left leg, which had invalidated him for six weeks with abscesses. No bone had come away; but the tibia subsequently remained thickened. He then (fourteen years ago) had some venereal trouble—warts on the penis—but no history of true syphilis. In 1873, he had chronic synovitis of the left knee-joint, which subsequently remained stiff. He, however, had since followed his employment of a gas-stoker. Last Easter, the right arm was swollen; and the urine became dark-coloured, more especially in the evening. Being admitted to Guy's Hospital, an osteo-arthritis condition was found to prevail extensively in both knees and in the left elbow, less markedly in the right wrist. Both femora, the left tibia and right fibula, the right radius and ulna, both clavicles, and all the ribs were greatly thickened; the head was massive, and other bones were less affected. The urine was slightly albuminous, was usually clear, and its specific gravity varied between 1020 and 1025. The treatment consisted of iodide of potassium and cinchona. A purpuric eruption of the skin had for many months past frequently recurred. The treatment decreased the size of the joints, but apparently had no such effect on the bones. The iodide being discontinued, the joints increased in size; and were again lessened when the remedy was taken. The biniodide of mercury also appeared to exercise a beneficial effect. Mr. Howse remarked on the possible relationship of this case to those of osteitis deformans described by Sir James Paget. In these cases death had mostly come from some cancerous disease; this man's mother had died of cancer. Sir James Paget had seen this man; and, from the absence of curvature of the bones and from the fact of his improvement under the iodide of potassium, had considered this case to be essentially dissimilar from his cases of osteitis deformans, and had thought the bone-thickening was probably due to some constitutional disease, most likely syphilis. There was, however, no distinct history of syphilis; and Mr. Howse suggested that the case was similar to those described by Sir James Paget, and that the curvature might come on in time, as the patient became older.

*Osteitis Deformans.*—Mr. HOWSE also showed a specimen of this disease from an old lady, whom he had seen in consultation with Dr. R. Harris of Hackney. The patient, aged 65, had always enjoyed good health until two years ago, when constant pain in the right leg occurred, and the tibia became slightly bent. In September 1875, when seen by Dr. Harris, she had intense pain at the inner side of the head of the tibia, with aching in the shaft of the bone. There was no swelling of the bone anywhere, but the shaft was bent. She could walk without much difficulty. That autumn a small rounded swelling appeared on the inner side of the head of the tibia, firm, but fluctuating, much resembling an enlarged bursa. The pain now diminished, as the swelling increased. A small trocar being introduced, drew off a small quantity of thick serous fluid, at first clear, afterwards blood-stained. Bleeding to the extent of about an ounce occurred during the night from the puncture. The swelling at first became less tense, but in a few days was as large as ever, and larger, and fine blood-vessels ramified over its reddened surface. Mr. Howse, being called to see the case, detected faint pulsation in it. The patient being anaesthetised, the tumour on being opened was found to be a soft mass occupying the centre of the upper epiphysis of the tibia. The limb was consequently amputated through the lower third of the thigh under the carbolic spray. The wound healed primarily. The patient quite recovered, and was able to get up and move about. Five months subsequently, serious lung-symptoms supervened, of which the patient died in a few weeks. An inspection of the body could not be obtained; but the patient doubtless had recurrence of the tumour in the lung. No curvature or thickening of any other bones could be detected. Sir J. Paget had examined this specimen, and thought it belonged to the osteitis deformans group. The tumour in the head of the bone was a large spindle-celled sarcoma. Under the microscope, the Haversian system of the bone resembled sections of cancellous tissue. The walls of the cancelli were thick, and abundantly sprinkled with bone-corpuscles. The cancellous spaces contained a few fat-vesicles, rather more connec-

tive tissue elements than usual, and germinal cells unlike ordinary marrow-cells, but resembling similar elements usually seen in cases of scleriosis of the skin. Amongst these were many groups of yellowish pigment masses, probably derived from extravasation of blood. This condition was possibly allied to the tendency to purpura manifested by Mr. Howse's other patient exhibited earlier in the evening. Mr. Howse remarked that the so-called cancer which had co-existed in so many of Sir J. Paget's cases was probably a form of malignant sarcoma, and ought to be essentially associated with the change which the bone itself had undergone. Bone itself being a form of hardened connective tissue, the thickened softened condition visible in these bones might, as Dr. Goodhart had supposed, be regarded as a form of bone-tumour. On the other hand, under favouring circumstances, an ordinary inflammatory cell might possibly grow up into a regular spindle-cell, and form the basis of spindle-celled sarcoma. A man was recently under Mr. Howse's care who had symmetrical tumours on the backs of the forearms. These were both excised. The centre of one, the larger, growth showed definite spindle-celled elements; at the margin, these were less distinct, and formed such an infiltrating mass that it was impossible to remove the whole growth. Nevertheless, under the influence of biniodide of mercury, the whole wound healed, and all trace of the tumour disappeared; and had not recurred. There was no history of syphilis in that patient. This observation might help to connect the views of those who, like Dr. Goodhart, considered the whole bone-thickening due to a species of bone-tumour, and of those who, like Sir J. Paget, thought the bone diseased was a degenerative osteitis, and that the co-existence of the tumour in so many instances was more or less accidental. Mr. Howse was inclined to regard the bone-thickening as due to an "osteitis deformans"; and thought the tumour form of the disease was related to the osteitis as definitely as a persistent chronic eczema of the nipple is related to a carcinoma developing within the mammary gland.

*Sarcomatous Tumours in Various Bones associated with Hyperostosis.*—Dr. GOODHART brought forward two cases. The first was that of a woman aged 60, under Dr. Wilks's care. There was no family history of cancer, and, till six months before her admission into Guy's Hospital, she had enjoyed good health. She then began to waste, and for three months she had had pains in her back and hips. She was admitted for paraplegia, and died soon afterwards with suppurating kidneys. The *post mortem* examination revealed a large sarcomatous tumour growing from the blade of each ilium; a similar growth about the lower part of the spine, which had encroached upon the spinal canal and caused paraplegia; osteo-arthritis changes about many of the vertebrae; and a skull, the thickness of which reached four-fifths of an inch, the bone being heavy but porous, and at two parts affected with circular patches of new growth. The long bones were not affected. In the second case, the skull was rather thick also; its diploe gone; the bone heavy and yellow looking. The right ilium was dense and heavy; some of the bones showed osteo-arthritis changes; and, in addition, a periosteal sarcoma affected the ilium, spine, ribs, femur, clavicle, mediastinal glands, and both suprarenal capsules. The man, aged 55, was under Dr. Moxon's care at Guy's Hospital. There was no family history of cancer; and he had enjoyed good health—he had had gonorrhoea—till six or seven months before his admission, when he was attacked with pains in various parts. No tumours were felt till a late stage of his illness; and he died ultimately of exhaustion. Dr. Goodhart remarked that the interest of these cases lay in their bearing upon the disease which had lately been described by Sir James Paget as osteitis deformans. They did not, it was true, show a very marked osteitis anywhere, except in the cranium in one; but, nevertheless, they were probably related to such cases, and the very fact that they were prominently tumorous and not hyperostatic added to their value. Sir James Paget, and with him Mr. Barlin, considered the disease to be one of chronic inflammation, arriving at this conclusion both from its clinical history and minute anatomy. Sir James Paget, when stating the fact that several of the recorded cases had ultimately developed cancer, did not think that, at present, the evidence was sufficient to warrant anything further than that it might or might not be a coincidence. Now, however, with Sir James Paget's cases, Dr. Gayley's, and the two now brought forward, six out of eight cases had developed some malignant tumour; and this was a proportion so remarkable as to destroy the probability of mere coincidence, and sufficient to link the two conditions closely together. Assuming that they were connected, was Sir James Paget's hypothesis of a chronic inflammation still tenable? It must be admitted that it was. It might be that, as a result of the chronic irritative overgrowth, the feature of malignancy was gradually evolved. Thus, the two might be directly connected; and this was a view quite in accord with the opinion of many at the present time, that malignant growths were local and not constitutional. (Sir

James Paget would probably not admit any such interpretation of the facts.) Dr. Goodhart, however, suggested another explanation of osteitis deformans; that it was a generalised form of tumour of the bones, and not a chronic inflammation. He took this ground for several reasons. First, the formation of the tumour in these cases had not by any means always been in the diseased bones; in one case, it was in the dura mater; in another, in the mediastinum and lungs, etc.: a point altogether against the evolutionary hypothesis of chronic inflammation turning into cancer, and in favour of a tendency on the part of many tissues to overgrow. These two cases also suggested in their subordination of the so-called chronic inflammation to the growth of tumours that the two processes were one and the same, and that what in one case was a chronic process of growth lasting for years might in another be so active as to lead to a spontaneous outburst of growth in many parts with great rapidity, and under such circumstances but very little hyperostosis could of necessity arise. Not only so; other pathological conditions showed very precise analogies to this. Mr. Butlin's case of multiple sarcoma, read at a late meeting of the Society, was in point; the subcutaneous tissue exploded into sarcoma all over that boy's body; or, to take another case, fibrous tumours were found growing all over the skin, or on many of the nerves; and more exact still, perhaps, was the disease called lymphadenoma. The lymphatic tissues and glands slowly hypertrophied in the course of years, very like a chronic inflammation; at other times, they all began to grow suddenly, rapidly, and malignantly; at other times, the slow process turned into the rapid one; so that there did seem to be in several tissues a tendency to go wrong as a whole; and, since in the one case there had never been any objection to regard the process as one of tumour, neither need there be any difficulty with regard to the other. This view, if it were correct, had an interest apart from the particular disease to which it was here applied; and it was quite possible that many growths, which were now said to be secondary and due to infection from some primary focus, were, in reality, spontaneous outbursts in other parts of the body in no way connected with any so-called primary source.

The PRESIDENT said that these cases were of great interest, as bearing on the pathology of the disease described by Sir J. Paget.—Mr. MYERS protested against the assumption frequently made, that, because a man had been a soldier, therefore he must have had syphilis. On the contrary, he believed that amongst men in the army syphilis was less known than amongst men of the same class in civil life. Certainly the worst forms of constitutional syphilis were less frequently seen in military than in civil hospitals.

## MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, DECEMBER 5TH, 1877.

H. D. LITTLEJOHN, M.D., Vice-President, in the Chair.

*Excision of the Knee.*—Professor SPENCE showed a specimen bearing on excision of the knee-joint. The patient had his knee-joint excised, with an apparently successful result. After he had been out of hospital for some time, he returned with an abscess in the upper part of the popliteal space, from the presence of diseased bone. This was gouged out twice, but, as the boy was losing flesh, he was obliged ultimately to amputate. The specimen showed in front the firm cicatrix and on section the firm bony union of the divided parts, as well as the recurrence of the disease at another point. He also showed the parts removed, in excision of the knee-joint, in the case of a young woman, who, while she had considerable pain, did not suffer from much constitutional disturbance. She was doing well.

*Disease of the Femur.*—Mr. SPENCE showed a specimen of disease of the trochanter, lower part of the neck of the femur, and digital fossa. The patient came in with a large abscess of the thigh, which had opened about four inches below the great trochanter. This was freely incised and the parts were carefully examined. No evidence of disease could be found, and the joint was freely movable. The patient, however, suffered from pain when the extension-apparatus was removed; and further examination showed existence of disease as above stated, the cartilage of the joint being sound. Mr. Spence excised the joint, and the case was now doing well.

*Amputation of Foot for Tumour.*—Mr. SPENCE showed preparation of amputation of the foot for tumour, involving the metatarsal bones of the second and third toes. The patient came in a week ago, and stated that a small tumour had existed there for some time, and had been operated on or incised; but that of late it had grown rapidly. The rapidity of its growth, its dark colour, and the emaciation of the patient, pointed to its being malignant; but the existence of the small tumour for some time previously was against this. As little of the foot

could be saved, he amputated by Key's method, disarticulating partially, and then sawing through at the internal cuneiform bone. On examination, there was seen to be softening and opening out of the metatarsal bones. On microscopical examination, Dr. D. J. Hamilton found a hyaline appearance, with stellate cells. A specimen from the interior of the tumour showed broken-down texture, fat, and blood. It, therefore, seemed not so malignant; but it was rare to meet with so much congestion and extravasation in a simple tumour. The pain was due to pressure on nerves, as a cutaneous nerve could be seen running across the growth.

*Congenital Malformation of the Leg.*—Dr. CRAIG showed a preparation of the right lower extremity of a child, which had died twelve hours after birth. It had several malformations. The fibula did not articulate with the tibia at the knee-joint, and there was talipes varus. The tibia appeared to end two inches below the knee, with a puckered appearance as of a cicatrix. There was thus no bony connection between the knee and ankle-joint. He hoped soon to have the limb dissected, so as to ascertain its exact structure. The limb had been preserved in a solution of chloral, ten grains to the ounce, with the result of being natural in appearance and free from putrefaction.

*Addison's Keloid.*—Dr. GRAINGER STEWART then showed an interesting example of Addison's keloid, in a female child of about ten years old. It was most marked over the dorsum of the feet, and was also seen in the arms and hands.

*Malposition of the Testes.*—Mr. ANNANDALE showed a photograph of a rare congenital malposition of the testicle in the perinæum, which had been for the first time successfully treated by operation. One or two cases were on record where the attempt had been made to replace the displaced organ, but always without success. He believed his own success to be due to the use of antiseptics, by Lister's method. He made an incision over the displaced testicle and drew it out. The part of the gubernaculum testis, usually attached to the bottom of the scrotum, was in this instance fixed to the ischial tuberosity. He incised the scrotum and placed the testicle there, retaining it by means of a catgut stitch. At the same time, he stitched up the opening in the perinæum also with catgut. The result was satisfactory, and the testicle was now in all respects like the one on the opposite side.

*Supernumerary Auricle.*—Mr. ANNANDALE showed a supernumerary auricle from the side of the neck. The patient had a small pediculated tumour about two inches below the lobe of the ear. At first, it looked like a small fibrous tumour; but, on examining it and making a section, cartilage was found.

*Stricture of the Oesophagus.*—Dr. P. A. YOUNG read notes of two cases of stricture of the oesophagus, with pathological report by Dr. D. J. Hamilton. One of the cases was a malignant stricture, in which Dr. Young and a surgeon had failed to pass a bougie, though, at the *post mortem* examination, the stricture admitted the forefinger. The other case was one of simple organic stricture. Both had died with symptoms of acute chest-affection at the end.—Dr. LITTLEJOHN asked if any cause could be assigned for the ulcers. In pathological museums, such were due generally to swallowing some impure alkaline solution.—Dr. SANDERS said that pneumonia was not uncommon. The cause given was the opening into the left bronchus. The pneumonia, however, was in the right lung. In some cases, it seemed to be due to an extension of the inflammation; but in others, the theory of some influence through the vagus was fairly borne out. The cause of such strictures needed investigation. Usually, a caustic solution was accidentally swallowed, and then the stricture was at the upper end. Sometimes, however, it resulted from an overdose of medicine. He remembered a case where stricture followed the swallowing of the whole of a medicine containing an excess of acid, prescribed by a distinguished physician. Stricture at the cardiac orifice would probably not occur, unless the mucous membrane above were affected. Mechanical irritation might lead to chronic inflammation of the submucous coat, and consequent stricture. When the stricture did occur, then the dilatation, hypertrophy, and ulceration ensuing were easily understood.—Mr. SPENCE asked if Dr. Young had tried a medium-sized bougie before attempting a fine one. It was exceedingly rare to meet with simple oesophageal stricture at the cardiac end of the stomach: it was generally due to swallowing acids. In the University Museum, there was a preparation of an oesophagus, where the patient had swallowed sulphuric acid. The mucous membrane above the cardiac orifice was corrugated, and near it it was charred.—Mr. ANNANDALE said that, while Dr. Young and Mr. Chiene had extreme difficulty in passing a small bougie during life, a finger passed in at the *post mortem* examination. This was probably due to spasm; and the question was, whether they could not get the instruments more easily passed in such cases by giving chloroform.—Mr. SPENCE said that chloroform had been given in hysterical cases.—Dr. SINCLAIR had listened with interest, especially to the second case,

as last October he had one similar to it. The patient was a married woman, who stated that she had gone to the Infirmary, where a large œsophagus bougie had been passed, causing her great pain. The diagnosis arrived at was evidently hysterical stricture, as tincture of assafoetida had been prescribed. The patient, however, became emaciated, and died six weeks afterwards from double pneumonia. On *post mortem* examination, a small ulcer was found above the cardiac end of the stomach, but no evidence of malignancy. The difficulty in swallowing was, therefore, entirely due to reflex spasm.—Dr. A. G. MILLER said that, some years ago, he examined several cases of urethral stricture, and found the mucous membrane healthy, but puckered, with the stricture in the submucous tissue. He believed that in many cases the mucous membrane was healthy, but rugous. This was important, as it explained how, by Holt's method, a stricture could be split without bleeding.—Mr. BELL remembered that the late Mr. Edwards had shown to the Society a case where there was a tight stricture above the cardiac orifice and a hernia of the mucous coat through the muscular walls.—Dr. CADELL had removed a piece of bacon from the œsophagus of a woman, who had constriction caused by her swallowing potash when a child.—Dr. GRAINGER STEWART had noticed two results when he was pathologist to the Infirmary. There might be pneumonia near the stricture from extension, or suppuration around it, so that the patient died of pyæmia, with metastatic abscesses on the lungs and elsewhere.—Dr. YOUNG thanked the members. Dr. Sanders had pointed out that the pneumonia was in the opposite lung from the perforation. The perforation, however, was very near the bifurcation of the trachea; and, therefore, matters could pass into the right bronchus. He had used a small stomach-tube first. He would have employed chloroform had he suspected ulceration.

*Treatment of Ununited Fracture.*—Dr. FINLAY read a paper on the treatment of certain cases of ununited fracture, based on a case in which, much of the tibia having been lost by traumatic necrosis, he had cut out a piece of the fibula; and thus allowed the ends of the tibia to come near and the limb to unite, though shortened.—Mr. SPENCER remarked the case was interesting as to the cause of non-union, viz., loss of part of the tibia, the fibula remaining entire. Still there might be cases of compound comminuted fracture of the tibia, with union, after necrosis. This depended on the nature of the injury. In gunshot and railway and tramway accidents, there was such damage to the periosteum that union was impossible. In one case, where rest for eighteen months had proved ineffectual, he got union by Miller's method. In another case, in 1854, he bent the arm, projected the fragments through an incision, and clipped off the ends. The principle was to fracture and not to dissect, and in this case he had perfect union.—Mr. ANNANDALE said that, in a case of his own, he had wired both radius and ulna, so as to prevent immobility and allow pronation and supination. He would suggest that the leg should still be kept in starch.—Dr. FINLAY thanked the members for their criticisms.

*Injury of Head, with Anomalous Symptoms.*—Mr. BELL read a report of a case of head-injury, presenting anomalous symptoms. The patient had been injured in a brawl. He was first unconscious, then slowly recovered a measure of intelligence; then, from the fourteenth to the twenty-first day after the injury, he passed into a most alarming state of torpidity, in which he passed urine and feces in bed, and appeared to be dying. He had partial paralysis of the face, external squint, and certain curious peculiarities in his voice and gesture. The pulse and temperature were low all through; and he eventually recovered.—Dr. CLOUSTON had seen three cases of general paralysis following such injuries.—Mr. SPENCE said there might be slight effusion at the base of the brain.

## BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

DECEMBER 13TH, 1877.

SAMPSON GAMGEE, F.R.S. Edin., President, in the Chair.

*Obstructive Jaundice and Cancer of Liver.*—Dr. BALTHAZAR FOSTER showed a liver, taken from a patient who had died in the General Hospital. The man had been for years a heavy drinker, and five months before death had, while in Jersey, indulged freely in brandy and rum. This excess was followed by jaundice and an attack of hepatic colic. When the patient was first seen, the liver was enlarged, with well-defined edge, slightly granular to the touch, but free from all tenderness, as it remained throughout. The gall-bladder could be distinctly felt, distended with bile. The case was regarded as enlargement following obstructive jaundice; but this opinion was modified in favour of malignant mischief, on account of the rapid increase in the size of the liver after he had been some time under observation. The man died three months after admission. The liver weighed thirteen

pounds, was smooth on the surface, dark olive-green in colour, with spots of creamy colour, due to cancerous growth. The cancer appeared to have begun in the neighbourhood of the common duct, which was enveloped by a cancerous mass. The orifice of the duct was, however, obliterated by fibrous tissue, and a gall-stone was found obstructing the cystic duct. These conditions explained the sequence of phenomena observed during life, viz., hepatic colic and jaundice, enlarged gall-bladder, not subsequently increasing in size; enlarged liver, smooth and not tender; and later on, as cancer invaded the liver-tissue, rapid enlargement of the viscus. There was no cancer in any other organ. Sections of the liver were shown under the microscope by Dr. Saundby for Dr. Foster.

*Myxoma of the Uterus.*—Mr. LAWSON TAIT showed a large œdematous myxoma uteri, which he had removed successfully by abdominal section, and which, immediately after removal, weighed a few ounces over twenty pounds. It was the fourth case in which he had operated; two of these had recovered.

*Peyer's Patch.*—Dr. SAUNDBY showed a specimen of a Peyer's patch, in the stage of early swelling, taken from the body of a child who died of hyperpyrexia within twenty-four hours after the first symptoms of illness appeared. He also exhibited a specimen of acute enteritis from a fatal case of diarrhoea.

## SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

NOVEMBER 29TH, 1877.

G. S. TAYLOR, Esq., President, in the Chair.

*Removal of Upper Jaw, without External Incision.*—Mr. ARTHUR JACKSON introduced a young woman, from whom he had removed the superior maxilla for myeloid disease. No external incision had been made. He had practised the same method in another case.

*Extraction of Cataract by a Shallow Lower Flap.*—Mr. SNELL made some brief observations on extraction by this method. The puncture and counter-puncture were made in the sclero-corneal junction, just below the centre of the pupil. The edge of knife was turned directly forwards, and the section completed by cutting outwards; the summit thus lying midway between the pupil and lower border of cornea. Three patients were introduced who had been operated on by this method; two of them in both eyes. Anterior synechia was not thought to be so frequent after the operation as some supposed.

*Urinary Test-Case.*—Dr. DE BARTOLOMÉ exhibited Dr. Batten's pocket urinary test-case.

*Piece of Glass in Bronchus.*—Mr. LAVER related the case of a boy who had swallowed a piece of glass. He was under Mr. Jackson's care in the Infirmary. Tracheotomy was performed, but it was found impossible to detect the foreign body. He died about a month subsequently, and, at the *post mortem* examination, the piece of glass was found in the right bronchus.

Dr. DYSON exhibited the morbid specimens from a case of Cirrhosis of Liver, with impacted Gall-stone.

Dr. DREW briefly related a case of Pulmonary Embolism, caused by injury.

*Pyæmia.*—Mr. JACKSON read a paper on two cases of pyæmia. In one case, there was disease of the metatarsal bones; in the other, of the sacro-iliac joint from recent injury. The cases were interesting in the conspicuous absence of symptoms which are generally considered essential to diagnosis, rather than in the presence of anything unusual. In one case rigors were absent, in the other present; in one case perspirations frequently occurred, in the other entirely absent; in one case also there was no wasting, in the other it was conspicuous. The temperature was normal between the rigors in one, while in the other case it was never under 100 deg. Fahr. In one case there was communication with the external air, in the other no such communication. In the history of both cases, constitutional dyscrasie prominently figured. Mr. Jackson pointed out the important part which dyscrasie played in the etiology of the disease. He insisted also on the frequency of injury to bone as a cause of the disease; and objected to the term pyæmia, as likely to prolong our confused knowledge, if not misdirect future investigation.—An animated discussion ensued, in which several members joined, and, on the motion of Mr. Snell, the debate was adjourned.

DECEMBER 13TH, 1877.

G. S. TAYLOR, Esq., President, in the Chair.

*A Case of Scalping.*—Dr. KEELING related the notes of the case, and afterwards introduced the patient, a young woman. Her hair had been caught in some revolving machinery, by which she was lifted from the ground and the whole scalp torn off. A number of large pieces of bone

exfoliated, and it did not finally heal until four years after the accident. Photographs of the case were also exhibited.

**Removal of Portion of Silver Catheter from Bladder.**—The patient was a man aged 75, with prostatic enlargement, and had been accustomed to catheterise himself. Mr. Jackson removed the portion of catheter by the operation for lateral lithotomy. The case, however, terminated fatally, and the piece of catheter extracted was exhibited, measuring about five inches in length.—Remarks were made on the case by Mr. PYE-SMITH, Dr. DE BARTOLOMÉ, Mr. DYSON, and Dr. KEELING.

**Deformed Forearm and Hand.**—Mr. SNELL exhibited the dissected specimen, from a male subject in the dissecting-room at the Medical School. There were a rudimentary thumb and index finger. The radius passed obliquely across the forearm, did not directly articulate with the carpus, but was separated from it about an inch and connected by a loose capsule. The ulna terminated some little distance above the radius in a hooked extremity.

**Calculus Removed from Urethra.**—Mr. W. M. JONES exhibited the specimen, and stated that he had removed it from a child by means of a loop of steel piano wire.

**Intracapsular Fracture of Neck of Femur.**—Mr. RECKLESS showed the specimen, which was from the body of a woman aged 73. Fracture had occurred two months before death. There was no attempt at union.

**Imperforate Anus.**—The rectum terminated in a *cul-de-sac*. Dr. HARGREAVES exhibited the specimen, and stated that the child lived fourteen days.

**Rupture of Uterus in the Third Month of Pregnancy.**—Mr. EDWARD SKINNER related the case. The patient was a young woman aged 23. The *post mortem* examination disclosed a rupture of body of uterus at its upper and posterior part; the placenta was protruding, and the foetus was in abdomen. There was no history of a fall or blow, and the rupture was thought to be the result of softening. It was the second pregnancy.—Dr. KEELING remarked on the rarity of rupture at this period of gestation, and on the bearing of this to the softness of the uterine walls.

**Adjourned Discussion: Pyæmia.**—The debate on Mr. Jackson's paper was resumed by Mr. SNELL, and continued by the PRESIDENT, Mr. JONES, Mr. B. WALKER, Dr. DYSON, and Mr. JAMES. Mr. JACKSON replied.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, DECEMBER 8TH, 1877.

EDWARD HAMILTON, M.D., President, in the Chair.

**Dislocation of Spine.**—Dr. T. E. LITTLE presented a case of dislocation of the spine, in a young man aged 18, who died eighty-five days after the receipt of the injury. He fell down the hold of a vessel on his back and shoulders. He was able to walk into the hospital with assistance. There was complete motor, and partial sensory, paralysis in the upper extremities; but, in the lower limbs, no lesion of either motion or sensation existed until two months had elapsed. Marked flushing of the face, etc. (vaso-motor paralysis), was observed. On the tenth day complete atrophy of the muscles of both forearms set in, so that Cruveilhier's paralysis and "la main en griffe" became well marked. The skin of the hands and fingers assumed a glazed appearance. Paralysis of the intercostal muscles led to dyspnoea in expiration, inability to expectorate, and finally apnoea and death. The urine had been acid until a week before he died. There was a dislocation of the fifth from the sixth cervical vertebra, the articular processes of the fifth being hitched in front of those of the vertebra below. The spinal canal was narrowed to half its normal lumen. A greyish spot existed in the anterior columns of the cord. There was intermuscular wasting.—Dr. BOOKEY alluded to Dr. McKendrick's observations on colloid degeneration in the spinal cord in cases of trauma.—Dr. W. G. SMITH regarded the case as specially interesting, because it showed that the glossy appearance of the fingers, noted by Sir James Paget in peripheral nerve-lesions, may occur also in central paralysis.—Dr. FINLEY asked whether the external or internal intercostals were the more paralysed.—Dr. LITTLE said both were extremely atrophied.

**Saccular Aneurisms (Virchow).**—Dr. NIXON showed the brain, lungs, and kidneys of a woman who had died of apoplexy, the result of an extensive meningial hæmorrhage from a saccular (miliary) aneurism situated on the right middle cerebral artery. The left artery also was the seat of a similar aneurism. The kidneys were intensely congested and the lungs were engorged with blood; this functional hyperæmia being symptomatic of the lesion in the neighbourhood of the aneurism which had ruptured.

**Lesions in Morbus Coxæ.**—Dr. E. H. BENNETT exhibited the head and

neck of a femur, removed by excision from a boy nine years of age, suffering from morbus coxæ in the stage of suppuration. He also exhibited the innominate bone and femur of the same patient, removed *post mortem* seven months after operation. The operation had been undertaken when abscess had been discharging for some time, and when the rapid progress of hectic fever indicated a speedy end to the case. The viscera were healthy at the time of operation. Marked relief followed the operation, the temperature and other febrile phenomena falling. This improvement was maintained for more than a month, when progressive disease of the pelvis was observed, with a gradual increase of suppuration, and finally the development of hepatic enlargement. The death occurred seven months after the operation. The femur was found healthy, the point of compact tissue which lay against the carious pelvis alone showing any disease. Extensive caries of the innominate, which had not at the time of operation extended outside the acetabulum, affected the dorsum ilii and all the surroundings of the acetabulum. An intrapelvic abscess also existed, springing from the perforated floor of the acetabulum.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 27th, 1877.

Campbell, William Frederick, Chippenham Road, St. Peter's Square  
Lloyd, George Jordan, South Wreath, Birmingham  
McCarthy, George, Kinnare, Ireland  
MacIlhatten, Alexander, Treorky, South Wales

The following gentleman also on the same day passed his primary professional examination.

Dunlop, James Hay, Guy's Hospital

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, January 3rd, 1878.

Clarke, Thomas Furze, Richmond, Surrey  
Dingley, Allen, Arzyle Square, King's Cross  
Ellison, Frederick William, Leytonstone  
Richardson, Richard Tippetts, Kingston-on-Thames  
Thomas, Richard Weddall, York

The following gentlemen also on the same day passed their primary professional examination.

Baber, Henry Aitkens, Guy's Hospital  
Collins, George Duppa, King's College Hospital

## MEDICAL VACANCIES.

THE following vacancies are announced:—

**BALROTHERY UNION.**—Medical Officer for the Lusk Dispensary District. Salary, £125 a year as Medical Officer, and £20:16:8 as Sanitary Officer, with the usual Registration and Vaccination Fees. Election on the 19th instant.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.**—Assistant-Physician. Applications to be made on or before the 26th instant.

**DURHAM COUNTY HOSPITAL.**—House-Surgeon. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 26th instant.

**IPSWICH BOROUGH LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.

**KENT COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer and Dispenser. Salary, £165 per annum, with furnished apartments, milk, vegetables, washing, and attendance. Applications to be made on or before February 6th.

**NEWCASTLE-UPON-TYNE INFIRMARY.**—Senior House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before February 4th.

**SALFORD and PENDLETON ROYAL HOSPITAL.**—House-Surgeon for the Pendleton Branch. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 14th instant.

**SUNDERLAND and BISHOPWEARMOUTH INFIRMARY.**—Senior House-Surgeon. Salary to commence at £80 per annum, with board and residence. Applications to be made on or before the 24th instant.

**WARMISTON UNION.**—Medical Officer for the Longbridge Deverill District. Salary, £30 per annum. Applications to be made on or before the 14th instant.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ALLAN, James, M.B., appointed Senior House-Surgeon to the Northern Hospital, Liverpool, *vice* A. Craigmile, M.B., resigned.

\*COLLINS, Rowland H., L.R.C.P., appointed Medical Officer in Ordinary to the Bedford General Infirmary, *vice* George Wharton, M.D., Physician to the Infirmary, deceased.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

## DEATH.

LANG, John, M.D., of Southport, aged 49, on January 5th.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY.....	Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.
TUESDAY.....	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY..	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.
THURSDAY....	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.
FRIDAY .....	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
SATURDAY....	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY.—Medical Society of London, 8.30 P.M. Mr. Wordsworth will bring forward Six Persons having Congenital Displacement of the Crystalline Lens; Dr. Foulis of Glasgow will read a paper on Excision of the Larynx, and exhibit a patient on whom the operation has been performed.
- TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Wagstaffe: Dermoid Cysts along Branchial Fissures. Mr. Dowse: Case of Paralysis Agitans. Dr. Garlick: Diaphragmatic Hernia. Dr. Kallie: 1. Phosphatic Diabetes; 2. Gangrene of Lung with Lead-poisoning. Dr. Greenfield: 1. Aneurysm of Cerebral Arteries; 2. Aneurysm of Brachial Artery from Embolism. Dr. I. Burney Yeo: Rupture of the Aortic Valves. Mr. Bryant: 1. Prostatic Tumours removed during Lithotomy; 2. Impacted Fracture of Shaft of Femur. Mr. Nunn: Sequel to Case of Recurrent Sarcoma. And other Specimens.
- THURSDAY.—Harveian Society of London, 8 P.M. Casual Communications. Dr. Ashburton Thompson, "On the Pulse-rate considered in relation to *Pertum hæmorrhagæ*".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

THE following communications have been handed to the General Manager:—Mr. R. J. Baylon, Cork; Mr. G. H. Larmuth, Salford; Dr. John Easton, London (with enclosure); Mr. Henry Foxton, Bristol; Dr. R. Thorne Thorne, Mr. T. Wallace, Mr. J. G. Braden, Mrs. E. Bogle, and Dr. Frazer.

## LIP-READING.

We have had communicated to us, by Staff-Surgeon R. Nelson, R.N., a case illustrative of a method of teaching the deaf and dumb to comprehend the observations made to them by the process known by the name of lip-reading, which has been carried out with great perfection by Mr. Van Praagh at the Jews' Deaf and Dumb Institution, Fitzroy Square. The case was that of a seaman aged 21, who lost the hearing of one ear in 1874, while employed at gunnery drill, and that of the other in 1876, while similarly engaged. In less than three months' time, the sick berth attendant, by simply giving a more decided and slower motion to the lips than in ordinary language, made the patient understand everything he wished to convey to him. Shortly afterwards, some others of the ship's company achieved a like result. The observations of Mr. Nelson lead him to the conclusion that three things are necessary for successfully carrying out this system—namely, light, to enable the pupil to observe every lip-gesture distinctly; proximity of pupil and teacher; and that the pupil must have a full-face view of the teacher.

## INDIAN GUIDE.

SIR,—The book called *The European in India; or, Anglo-Indian's Vade Mecum*, by E. C. P. Hull and R. S. Mair, M.D., F.R.C.S.E., is published by Henry S. King and Co., of 35, Cornhill, London. The copy I have cost four rupees four annas in Bombay.—I am, yours, R. J. MAITLAND COPPIN.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

ADVERTISERS are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the JOURNAL Office or any stated address other than a Post Office.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATER IN DECEMBER 1877. The following are the returns made by Dr. C. Meymott Tidy to the Society of Medical Officers of Health.

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen used to Oxidise Organic Matter.	Nitrogen		Ammonia.		Hardness, (Clarke's Scale.)	
			As Nitrates &c		Saline.	Organic.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.		Grains.	Grains.	Degs.	Degs.
Grand Junction ..	19.20	0.134	0.120		0.000	0.008	12.6	3.7
West Middlesex ..	19.20	0.083	0.135		0.001	0.008	13.2	4.4
Southwark and								
Vauxhall .....	18.70	0.127	0.120		0.001	0.009	12.1	4.2
Chelsea .....	18.20	0.065	0.120		0.001	0.010	11.6	3.3
Lambeth .....	20.30	0.083	0.120		0.001	0.009	13.7	3.7
<i>Other Companies.</i>								
Kent .....	27.90	0.003	0.310		0.000	0.003	18.6	6.0
New River .....	20.20	0.036	0.150		0.000	0.007	14.3	3.3
East London .....	14.90	0.036	0.036		0.001	0.007	9.0	3.7

Note.—The amount of oxygen required to oxidise the organic matter, nitrates, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters, the quantity of organic matter is about eight times the amount of oxygen required by it. The water was found to be clear and nearly colourless in all cases but the following, when it was slightly turbid—namely, in that of the Grand Junction.

## MEDICAL ETIQUETTE.

SIR,—I have lately purchased a practice in the hamlet of S., separated from a town (T.) by a river (which during the day may be crossed either by ferry or by bridge). The latter way is a mile and a half round (there is also a high toll), and is the only available way at night. I am called up at night to see a patient taken, as I am told, suddenly much worse. The regular attendant (Mr. E.) from the town T., has not seen the patient for three weeks. I see the patient and prescribe a draught, telling them to send for Mr. E. in the morning, which they do. I get no call or thanks from Mr. E. Some time afterwards I am asked to go and see the same patient at 9 P.M., but refuse to go, telling them that if Mr. E. asks me or sends a card I will do so. They send over a messenger, who brings back medicine and a card for Mr. B., if it should be necessary during the night.

Is it the rule for a new settler to call on his neighbouring medical brethren first? It is bad enough to be called up to one's own patients during the night, but to be called up to other people's and get no thanks hardly suits my way of thinking, and my health not at all. If you would give an opinion, you would confer a great benefit on yours faithfully.

B. was fairly entitled to thanks from Mr. E. We think his best plan would be to seek an interview with Mr. E., so as to make some amicable arrangement with regard to the visiting of patients at night, in view of the difficulty of transit to which he refers.

SIR.—Mr. Box has, I repeat, brought a criminal charge against me, and has as yet, though challenged, produced no evidence in support. His letter in your last issue differs so materially from his former statement, that I am tempted to offer a few remarks thereon. In the first letter, Mr. Box says, talking of the injury to the ulna, "We were unanimously of opinion that this was not from fracture. It felt like a small node, and seemed probably to have been caused by pressure of the bone against some sharp edge, injuring the periosteum." Now, as Mr. Box is not a legal or editorial character, "We" must apply to all the gentlemen present as holding the opinion expressed in the passage. This week, however, he states the case thus: "Decided by all—1. Certain fracture of radius well united. (Who said otherwise?) 2. Ulna not broken opposite radius. (Quite true.) 3. Injury to the ulna not decided on, but pronounced obvious. (The pressure theory Mr. Box's own.)"

And now for the strangest part of the story. Mr. Box has had, in his possession since the examination of the man at Shrewsbury a certificate, signed by Messrs. Wood and Harris, stating the result of their examination of the arm in question. Why has Mr. Box not mentioned this fact, and forwarded the certificate for publication, instead of giving the opinion of these gentlemen second-hand? Messrs. Wood and Harris are both gentlemen of high standing, and in the absence of the accused party, would only give Mr. Box a certificate well considered, and stating the opinion of the case as they found it. Let Mr. Box forward this certificate, and any other evidence (not second-hand) he can.

I am much obliged to Mr. Box for leaving me to publish his third letter. It appears to me, however, more to prejudice the author than the case. Hoping Mr. Box will conclude his case, so that I can answer it as a whole, I am, Sir, yours obediently, R. LENT BENEFORD.

## AN APPEAL.

MR. SCARNELL wishes gratefully to acknowledge the receipt of the following amounts sent in answer to his appeal.

An Essex Practitioner .. .. .	1 0 0
Henry Stear, Esq., Saffron Walden .. ..	1 0 0
Dr. Holden, Preston .. .. .	0 5 0

1, Frederick Place, Penton Place, S.E., January 10th, 1878.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### PUERPERAL SCARLATINA AND PUERPERAL SEPTICÆMIA.

SIR,—The case of puerperal scarlatina recorded by Mr. W. T. Harries is not inopportune just now, when a discussion is going on in your JOURNAL in reference to Dr. Playfair's recent lecture. Upon this case, and upon the entire subject, bear with significance the words I used in 1875 in the Obstetrical Society (*Transactions*, 1875, p. 263): "I am led to these conclusions by a case of autogenetic puerperal poisoning under my care, in which most if not all the symptoms of scarlatina obtained, but which, recognising to be wholly the consequence of a morbid condition of the uterine system and of the lochia, I attacked by imitating the eliminative action of the uterus—viz., grasping the soft, spongy, uncontracted uterus with my hands, compressing it, and expelling some foul clots—and then washing out the womb and vagina by means of Higginson's syringe, Condy's fluid and warm water being used every two hours, till the lochia became quite inodorous. Had I, however, seen the patient for the first time, when those symptoms, apparently scarlatinal, were well developed, I might have erred in supposing I had a case of scarlatina to deal with, have treated it as such, and lost my patient; but being alive to the puerperal facts of the symptoms, I at once proceeded to deal with it as I have described; and the correctness of my diagnosis was evinced by the immediate improvement, commencing as it did from the very time I got rid of the offensive clots and washed away the foul lochia. All the group of evils in this case might be termed scarlet fever; yet all at once beginning to disappear under the cleansing treatment named, showed incontestably that the diagnosis was correct. Moreover, since her recovery I have made inquiries, and found no exposure to scarlatina was known to have occurred, nor did the malady manifest itself either before or since my patient's illness in the town where she lived." Here I would refer to Drs. Seaton and Howie's allusions to typhus and typhoid, being sometimes diagnosed as septicæmia, and would quote my words at the Obstetrical Society: "My mind has been exercised upon what I consider to be a fact—namely, that scarlatina and typhoid may originate in the same way; that is, from the same infecting source or poison; may be, in fact, the same poison developed in different persons, or in the same persons at different times and under different circumstances; the poison at one time determining to, or having an affinity for, the lymphatic and glandular systems, producing what we know as scarlet fever; at another time determining to, or having an affinity for, the intestines, particularly Peyer's patches, occasioning what we term typhoid fever. In this I am borne out by the independent researches of Dr. John Harley and of Dr. Tilt. Bearing in mind the life-symptoms which exist in scarlet fever, puerperal fever, and in typhoid, also the pathological conditions found after death—and how closely all are allied—if not in many instances actually alike, or so much alike as to make men pronounce different diagnoses, we can understand how readily scarlet fever can run into puerperal, and both into typhoid, and how the eminent Dublin physician, Sir Henry Marsh, came to suppose typhoid may originate puerperal fever; and, finally, how puerperal may clothe itself in the garments of scarlet fever, so that, as in Dr. Haine's and my case, the two affections are hardly distinguishable."—I am, etc.,

G. DE GORREQUER GRIFFITH, Senior Physician to the Hospital for Women and Children.  
January 1878.

#### HYDROPHOBIA: APPLICATION OF FLUID CAUSTIC.

SIR,—Permit me to state that I have on three occasions during the last few months applied nitric acid to dog-bites, by means of an ordinary pipette, which allows easy insertion to the bottom of the wound, and regulation of the quantity of acid used. The result has been satisfactory in each case.—I am, etc.,

Paignton, January 1878.

CHARLES PRIDHAM.

DR. CARLINE (Lincoln).—We believe that the House-Surgeon to a hospital is not entitled to a fee for giving evidence at a coroner's inquest. The question, however, is a strictly legal one, and could be better answered by a lawyer.

#### INFLUENCE OF MARRIAGE ON EPILEPTICS.

SIR,—Some letters on this subject have lately appeared, but the fate of the children of such marriages has not been noticed. Holding the appointment of medical officer to the Dingle Epileptic Institution, I was induced some years ago to make investigations on this point, and the results I presented in the form of a paper to the Liverpool Medical Institution. Briefly, the results were as follows. Of forty-one patients about whom information was forthcoming, the parents of thirty-two were either alive and in good health, or, if dead, were reported never to have had fits. The parents of six were epileptics; and of the remaining three, drunkards. That is to say, about one in six were the children of epileptics. But of those whose immediate parents were healthy—nine brothers and sisters—two cousins and two aunts were epileptic, thus bringing the hereditary influence more strongly to the front. Among these cases, there were thirteen who had borne children, who numbered together thirty-four. Of these thirty-four children, sixteen are alive and well, eighteen are dead, five being acknowledged as epileptics. From the evident reluctance shown in acknowledging the fact of their children having been epileptic, I have no doubt that the real state of affairs was much worse. Surely, however, there is enough to make a medical man cautious of how he advises marriage among those afflicted with this terrible disease. Indeed, should the legislature not step in to prevent such marriages?—I am, yours,

W. MACFIE CAMPBELL, M.D.

Liverpool, January 5th, 1878.

YOUNG M.D. asks:—Do the families of medical men suffer more from infectious diseases than those of others? He would like to have the opinion of his professional brethren on this point.

#### MEDICAL OFFICERS OF HEALTH.

SIR,—Please remark on the following. A. was formed into a sanitary district. B., the medical man at A., refused the post of medical officer of health, which was then offered to and accepted by C., a practitioner residing at a distance of five miles from A. In the meantime, another medical man comes to reside in A.; and the term of C.'s appointment having expired, the local board offered the appointment to the local man, on the ground that it is inconvenient to them that their medical officer of health should reside so far away. Is he (the local practitioner) acting unprofessionally in accepting the appointment?—Yours obediently,

January 1878.

MEDICAL OFFICER OF A DISTRICT.

In the circumstances stated, supposing they are all fully statd, we can see no impropriety in the local practitioner undertaking the duties of medical officer of health.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### DIPHTHERIA.

SIR,—Dr. Maunsell, in his letter to you in the JOURNAL of the 5th instant, referring to croup and diphtheria, does not say how simple, acute, and specific inflammations are to be distinguished. For my part, I am inclined to think that diphtheria, croup, and acute catarrhal laryngitis may be manifestations of the same blood-poison. Dr. George Johnson considers that croup and diphtheria are the same, and Dr. Reynolds considers croup and laryngitis to be identical; and it is possible that both these authorities may be right; and, if we adopt the axiom that things which are equal to the same are equal to another, the conclusion is obvious. Perhaps each variety might be considered simple when there is no reason to suspect the action of a second blood-poison at the same time; and the converse. The subject is full of interest, and well worth a little discussion; and it is to be hoped that, if the Committee referred to by Dr. Maunsell have not arrived at a conclusion before the next annual meeting, they will at least do something in the way of reporting progress.—I am yours truly,

Southam, January 9th, 1878.

WALTER LATTEY, L.R.C.P.Lond.

Will Dr. Mueset kindly favour the readers of the JOURNAL with the age of the patient suffering from various aneurysms, whose case is so well described by him at page 12 in the JOURNAL of last week? D. B. BALDING.

#### OIL OF STAVESACRE IN PSORIASIS.

SIR,—I would wish to state how very efficient I have found the oil of stavesacre to be in cases of psoriasis and ringworm, as recommended by Mr. Balmanno Squire in the JOURNAL some time since. Mixed with olive oil, in the proportion of 1 to 8, and used two or three times as hair-oil, it completely devitalises the parasites and their ova. Two or three applications of the undiluted oil I have found to cure ringworm.—I am, etc.,

WALTER LATTEY.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Masbro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; etc.

## CLINICAL REMARKS

ON A

## CASE OF ANEURISM OF THE DORSAL ARTERY OF THE FOOT.

By WILLIAM S. SAVORY, F.R.S.,

Surgeon to St. Bartholomew's Hospital.

It is not always from great, or from what are sometimes called the best, cases in surgery that most may be learnt. To the patient, momentous issues may be at stake, and yet the duty of the surgeon may be clear and simple, and easily performed; or the case, to the patient, may be a comparatively trivial one, and may admit of remedy in various ways, yet the questions that arise thereon may lead up to some of the most difficult problems of surgery, and tax to the utmost all the ability, knowledge, and skill of the surgeon.

In illustration of this, I ask your attention to-day to a case in which the patient himself certainly regarded his trouble as a trifling one, although in its treatment some of the largest principles of surgery were involved. Let us, if you will, try to make the most of it now, by using it as a text for the discussion of some of them.

A man aged 49, a labourer, in good health, was on the 28th of March last admitted with a simple fracture of both bones in the middle third of the right leg. When the limb was examined, a pulsating tumour was discovered on the dorsum of the right foot, behind the angle between the first and second metatarsal bones, over the cuneiform—obviously an aneurism of the anterior tibial artery at this spot. The tumour was well defined; in size and shape, like the shell of a small limpet; throughout uniform, soft, and compressible. The investing structures were quite natural. All pulsation was controlled by pressure on the artery immediately above, and then the tumour forthwith became flatter and smaller in every way.

The man was fully aware of its existence. His wife said that she had for some years noticed the tumour when she washed his feet. He never thought much about it, but observed that it varied in size. He stated that six months ago it became larger, and then began to throb and became more troublesome, being painful on pressure. As he expressed it, the lump was very much in the way.

Now I need not tell you that this is an extremely rare situation for an aneurism. I never saw one here before, and I can find no record of a similar case.\* What was the cause of it?

Aneurisms, you know, may be due either to disease or to injury of the arterial wall. In either case, the tissues are so damaged, or the structure impaired, that the coats no longer afford adequate resistance to the pressure of the blood. The changes in the arterial tunics, which for the most part precede the formation of aneurism, are classed under the head of degeneration; and, although these changes are various in kind and degree, they all tend to a common result: they disqualify the artery, or the portion of it affected, for the part it has to play in the transmission of blood. Injuries, too, are of various kinds, and lead to aneurism in various ways. A wound of an artery, which may be a simple incised one, may heal; but the cicatricial tissue, from its very nature, may afterwards yield into an aneurism; or one or more of the arterial coats may be split, or cracked, or bruised, or otherwise damaged, and so give way before the force to which it is continually exposed. And, of course, injuries of all kinds are likely to tell with tenfold effect upon an artery already the subject of disease.

Now, in this case we failed to detect evidence of arterial disease in any part of the system. Auscultation gave no sign; and, wherever the arteries could be felt, their elasticity was unimpaired. The anterior tibial itself along the dorsum of the foot was quite natural to the touch. I should say it even gave the impression of being a remarkably healthy vessel. It was, perhaps, rather large, but without a trace of rigidity, and the pulsation was in every respect normal. In these circumstances, you see it was very improbable that the artery had been the seat of disease where the aneurism now was. Although I do not suppose observations have been very exact on this point, I think it must be rare that isolated patches of degeneration occur in distant arteries without evidence of disease elsewhere. Again, in extensive disease of the arterial system, which is common in advanced life, we

do not, in point of fact, as one of its effects, see aneurism of the distant arteries. How familiar we are with the evidence from touch of diminution of elasticity or undue rigidity of the walls of the distant arteries; and yet, from experience, we cease to think of the occurrence of aneurism consequent on this. Not that there can be any question of the relation of degeneration of the arteries, or impairment of their properties, to the occurrence of aneurism, as cause and effect; but the form of degeneration—the atheromatous—which usually tends to aneurism, affects, for the most part, the larger vessels; while in the smaller (though not in the smallest) arteries is usually seen that form of degeneration which is called calcareous. For these chief reasons, then, I conclude that the aneurism in the present instance was of traumatic origin. I believe it to have been the result of some injury which the artery had sustained there; not the result of a wound, or of any severe or sudden violence, for there was no evidence of this; but the artery, perhaps from rough pressure, as from a boot, may have been repeatedly bruised, and so gradually weakened. This idea was somewhat strengthened by the fact that at this spot, where the vessel rests on the cuneiform bone, it was rather more prominent than elsewhere. This, I need not say, is merely guesswork; and for the view I will only claim that there is, perhaps, less to be said against it than against any other suggestion.

When we talked of getting rid of what the patient himself called the jumping lump, he accepted the idea as a very pleasant one; and, on the whole, it seemed proper to interfere with it. It was not only a source of continual annoyance and trouble to the man, but it might at any time, either in the natural progress of the disease, or more likely because of injury, have ulcerated and given way, and so have led to severe hæmorrhage and other mischief, which would have called at once for prompt surgical measures in far less favourable circumstances. These considerations, with the probability that the aneurism might be obliterated without great risk of any kind, induced us to advise the man to have it treated. Indeed, the opportunity appeared to be a singularly favourable one. The fracture compelled confinement, and during this period the aneurism might be cured without further loss of time. Two troubles would thus be disposed of at once.

Obviously, various plans of treatment were open to us.

Pressure on the artery above, on the dorsum of the foot, with or without simultaneous pressure on the tumour itself.

The injection into the sac of some substance to coagulate the blood there, preventing at the same time undue extension of the coagulum or blockade of the vessels beyond by firm pressure with a metallic ring around the tumour. This is a plan which I have often adopted in the treatment of nævi.

Acupressure of the dorsal artery.

Ligature of the artery above, or of the artery both above and below; or ligature of the artery above first, and subsequently below if need be; or ligature of the artery both above and below, and then extirpation of the sac.

After duly weighing these several plans, we elected to try, in the first instance, as the simplest and safest, pressure on the artery above and over the tumour; and, that failing, ligature of the dorsal artery above, to be followed, if need be, after an interval, by ligature below.

In the first place, pressure, carefully watched, involved least risk of all; but that it would succeed appeared to be doubtful, because of the character of the aneurism; for, although the pulsation of the tumour was at once completely controlled by pressure upon the artery with the finger alone, yet, from its shape, compressibility, and collapse, it seemed to me to be an instance of true aneurism, as pathologists often use the term, or, as it may be, perhaps, better expressed, of aneurismal dilatation; that is, I believe it to have been an expansion of the entire arterial wall, all the coats having been dilated. I concluded, therefore, that we should hardly get coagulum in the sac from pressure; and that, therefore, pressure would be of only temporary advantage; that dilatation would recur when the blood was allowed to flow again with full force through the sac.

And, next to pressure, it seemed to me that ligature of the artery involved less risk than any of the other steps. I could see no advantage in acupressure over ligature on this score; while the injection into the sac of perchloride of iron, or of anything else, might set up destructive mischief which we could not easily control. Moreover, the ligature above, by permanently reducing the pressure on the sac, would, in all probability, prove an efficient remedy; or, at the worst, by subsequent ligature of the artery beyond, if need be, it could hardly be conceived that the disease would not be efficiently controlled. If that were done, there appeared to be no sufficient reason for interfering any further with the sac itself. We elected, therefore, as aforesaid, to try pressure first, and, that failing, ligature.

\* Quite recently, however, another instance has occurred. BRITISH MEDICAL JOURNAL, December 8th, 1877, p. 804: a case of "Spontaneous Aneurism of the Arteria Dorsalis Pedis, under the care of Mr. Adams."

But then came another question, which had to be considered at the time. If the artery were tied, it what place would it be best to apply a ligature? Now, you see this question involved the consideration of one of the most important principles of surgery. I need not tell you that, in tying an artery for the cure of an aneurism in what is now the ordinary way, as in the operation of Hunter, the ligature is placed on the vessel at some distance from the sac; and thus, while the direct current of blood is still cut off from the sac to an extent usually sufficient to cure the disease, the artery itself is injured by the operation at a spot where it is far less likely to be diseased or impaired than close to the aneurism; and hence the chance of its repair is proportionately greater. Now, had I been guided simply by these considerations, I ought to have tied the anterior tibial artery somewhere above the ankle-joint—say in the lower third of the leg; but then there were two important facts in the present case which had to be brought into the question. I have already given reasons for the belief that the aneurism here arose from injury rather than from disease. As I have said, I had every reason to believe that the rest of the artery was fairly healthy. Again, while pressure with the finger afforded proof that pulsation of the sac was controlled by arresting the stream in the artery just above, I could by no means be sure that ligature of the artery some inches higher up would be as efficient or even nearly so; for, as you all know very well, the farther we go from the heart outwards, the more ample is the collateral circulation in relation to the main trunks; and, as a matter of fact, had I tied the artery above the ankle in the leg, I must have had branches of importance between my ligature and the aneurism. Therefore the principles which are usually paramount elsewhere—as, for instance, in popliteal aneurism—were not in force here.

Well, then, fourteen days after admission, we began with compression. Pressure by means of a pad adequately supported, and sufficiently great to arrest its pulsation, was applied to the artery on the dorsum; and pressure tolerably firm, but equable, was applied also over the tumour through a thin layer of cotton-wool. This was kept up for several hours on more than one occasion, but not without discomfort to the patient, which gradually increased, and worried him so much that at length he begged earnestly for some change of plan. Indeed, the integument over the sac had become somewhat congested. Very soon after the pressure was removed, the tumour appeared unchanged, and, as the man expressed it, jumped as much as ever.

On May 1st, the fracture was found to be firmly united; the splints were removed, and the leg supported by a stiff bandage. Then, on the 11th, about a month after the trial of pressure, we tied the dorsal artery with an ordinary silk thread about an inch and a half or two inches above the upper margin of the aneurism. Immediately upon tightening the ligature, there was total arrest of pulsation in the tumour, and the sac became flaccid and soon shrank. All was quiet there for two or three minutes; but then the very feeblest pulsation in the tumour could be both seen and felt. The edges of the wound were brought carefully together by two sutures, and covered with oiled lint; a small pad of cotton-wool was placed over the aneurism, and the whole foot was lightly enveloped in a flannel bandage. It seems to me that the return of this feeble pulsation in the sac so soon after the application of a ligature is an interesting fact. How did the blood find its way to the tumour in sufficient force for this purpose? Was it through the tarsal or even the metatarsal branch which might intervene between the ligature and the tumour; or was it by a regurgitant stream supplied through the external plantar? I cannot be sure; but, as all this pulsation was arrested by slight pressure upon the distal extremity of the tumour, I suspect that the latter was the chief, if not sole, source of it.

But the next day the tumour was quite pulseless, and on the next it had shrunk so much that its prominence was hardly visible. From this time, it gradually subsided. For several days, it could be felt as a small firm nodule, hardly perceptible to sight, but easily defined by touch. The wound went on uninterruptedly well; it closed by direct union, except in its centre, where the double thread passed out. The ligature came away on the nineteenth day, and in two days afterwards the small channel it maintained was closed too. The man left the hospital on June 2nd, three weeks from the operation; and, after a holiday of six weeks at our convalescent home, the tumour was no longer visible, and could hardly be felt.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The fourth meeting of the twenty-second session was held at the Royal Kent Dispensary, Greenwich Road, on Friday, January 4th, at 8 P.M.: W. Johnson Smith, F.R.C.S. (President), in the Chair. Dr. J. Milner Fothergill read a paper on "Some Conditions which Simulate Organic Disease of the Heart".

## FOREIGN BODIES IN THE MEATUS.

By H. MACNAUGHTON JONES, M.D., F.R.C.S.I. & Edin.,  
Surgeon to the Cork Ophthalmic and Aural Hospital.

FROM time to time, it has occurred to me to see considerable damage done by rash and persistent efforts to extract foreign bodies from the auditory canal. The late Mr. Hinton has used the expression "aural surgery is simply surgical common sense, and needs comparatively little insistence on special points beyond that which a trained surgical instinct would suggest". "Common sense" and "surgical instinct" appear alike to be blunted when, with a remarkable absence of both, persons are yet to be found who can be rash enough to employ clumsy force and ill-contrived instruments in the removal of what often is, even after a prolonged residence, a comparatively harmless tenant from the external meatus. I would say a few words for common sense and surgical instinct, such as anatomical knowledge might suggest to anyone who pauses to reflect on the form and design of the external passage of the human ear. In the *child*, the meatus is remarkably narrow; it is mainly cartilaginous; it is often congenitally contracted; its skin-lining is directly continuous with the membrana tympani, and is intimately connected with the periosteum of the temporal bone; it is close to the dura mater, and closer still when gaps occur in the osseous canal. In the *adult*, the canal is more spiral, the osseous portion is proportionately larger; but the entire passage may be described as a coiled tube, about one inch in length, consisting of two portions, situated almost at an obtuse angle to each other, the junction of the two being marked by a peculiar contraction, any further closure of which, in consequence of inflammation or thickening, completely shuts off the bony internal pouch from the external funnel. Two things are at once evident from these simple considerations of the anatomy of the passage: first, that the direction of any extracting or expelling force must depend on the portion of the canal in which it is applied; secondly, that, having in view secondary consequences, and also the effect which inflammation has in frustrating our effort to remove a foreign body from the passage, we should employ no force which is in the least calculated to excite that inflammation. The greater the swelling of the epidermis with subcutaneous cellular effusion, and it may be peristitis, the greater the jamming the foreign body, whatever it is, gets. If it be hard and angular, this is more likely to occur than if it be smooth and round. If it be pushed into the pouch in front of the membrane, and the latter be contused in attempts to catch it, the more likely are we to have inflammation of the membrane and resulting perforation, with tympanic mischief. If the canal become so swollen that the foreign body cannot be seen, and its removal be still attempted, then the effects of this "groping in the dark" are more disastrous: further inflammatory mischief and tighter jamming. Now, what is it that, in the large proportion of cases, fixes foreign bodies in the ear?—attempts at removal. If the body do not occupy the calibre of the canal, it lies in it, and there is a space for the expelling force to be directed from behind on to it. If it be so large as to fill the entire calibre of the passage, which is rarely the case, it will, previously to being interfered with, in all probability lie loosely in the passage, its further entrance being arrested by the contraction of the wall. In my experience, the most frequent seat of the arrest of a foreign body is at the junction of the cartilaginous and osseous portions of the meatus. It becomes *arrested* here, or is driven beyond against the membrane by extractive efforts. Every touch of an instrument, no matter how gentle, sends it further in: each forcible effort tends to further *impaction*. Of course, there are some bodies so small and so shaped that it is a matter of no difficulty to catch them with a forceps and withdraw them. But I think it may be laid down as an axiom in aural surgery that, in the case of any arrested body in the meatus, where any space exists between the foreign substance and the wall of the meatus, the only agent which should be employed is water. If the body be impacted, or if it completely occlude the canal, much will depend on the nature of the body, its shape, the material of which it is composed, the length of time it is lodged, the presence or absence of inflammation, the kind of instrument at hand. It is my conviction that, in all recent cases, those quickly brought to the surgeon, syringing is the best means to adopt; in all cases where inflammation is not present, no matter how long the body lies lodged, syringing is also the best means; and, in cases where inflammation is present, I prefer, as a rule, to wait, using means to subdue it, with gentle syringing daily; and, if patience only be exercised, success in the end is almost certain. I prefer to make no remark here as to instruments. The instrument suited for one occupant of the canal will be found valueless for another. The shape and the

position of the foreign body are the two things which must be considered in the employment of any instrument. To avoid all force is the rule, never to be violated, let the circumstances of the case be ever so tempting.

I now desire to quote the following few cases out of many constantly occurring to me in hospital and private practice, which bear on the foregoing remarks.

Some years since, a child was brought to me with a shell in the meatus, where it was quite visible. It was one of those small yellow shells common on the beach. The convex surface was directed outwards. It completely filled the meatus, and was jammed in the contracted portion. Many attempts had been made to remove it, but all resulted in driving it further in, and its smooth surface rendered it impossible to catch it. I advised patience and syringing. There were both pain and inflammation when I saw the ear. Some catarrhal discharge subsequently formed. The ear was syringed daily. In about three weeks from the time I saw the case, the unwelcome guest suddenly came out while the ear was being syringed.

A gentleman was tickling his ear with a programme-pencil while at a ball. In doing so, the bone-top of the pencil remained in the ear. He fancied that he afterwards heard it fall out. Feeling, however, uncomfortable the next day, he sought advice, and the practitioner whom he consulted thought he saw the white flat surface of the bone-cap. Several efforts to seize it were made, giving him great pain. On the following day, these were repeated. The passage now became swollen and painful, and another surgeon was consulted, who, without expressing any opinion as to the presence or absence of the foreign body, wisely abstained from all interference, and directed simple washing out of the ear, and leeches to subdue the inflammation. After some days, I saw the patient. I found the passage contracted by the inflammation, so much so that no speculum could be inserted; there were considerable pain and complete deafness. However, with the otoscope and Politzer's bag, I satisfied myself that the probability was against the presence of a foreign body; but there was evidently a considerable perforation of the membrane. With care and treatment, he ultimately recovered, hearing the watch before he left me at twelve inches; but there has remained a permanent perforation in the membrane. This case was all the more serious, as the hearing in the other ear was impaired from childhood.

Some months since, a child was sent to me from the country by two medical gentlemen, with a glass bead in the ear. The bead was blue, diamond-shaped, and was taken from one of those "surprise packages" of sweets which are sold to children. The bead was in for several days, and resisted all attempts at extraction and syringing. The child was very restless, so I put her under the influence of chloroform and tried syringing, but in vain. The smooth, diamond-cut, conical end of the bead was turned out, and it was fixed in the passage. Keeping the child well under chloroform, with Dr. Grattan's assistance, I passed the sharp curved edge of a Critchett's cataract-scoop over the margin of the bead, between it and the wall of the meatus; I then was able to slightly turn it on its own axis. This gave me room to pass a loop of silver wire over the margin of the bead (as originally recommended by Mr. Hutchinson) and obtain a grip of it. But, after two or three efforts, the wire broke each time, and there was not room to pass a stronger wire behind the body. I, however, succeeded in getting a double loop of the thin wire over the edge, and finally brought it away. Some years since, a child was sent to me by Dr. Cummins of Cork with a spherical glass bead in the meatus, which completely filled the calibre of the canal. I thought that forcible syringing might, in this instance, by driving the body further in, do more harm than good; and, as the bead appeared not to be firmly impacted, and was not long in the passage, I thought of Brunel's plan for the coin in his larynx. Accordingly, I turned the child on her side, with the affected ear down, and, with assistance, while in this position, I placed the fleshy part of the thumb of my right hand (the body was in the left ear) over the opposite ear, the fingers being extended on the head, the inner side of the palm of the hand thus came above the auricle, on the temporal and parietal bones; by giving a few sudden jerks to the head in this position with the inner side of the hand, the bead dropped out.

A child was brought to me with a piece of chalk, which she had wedged into the passage. Efforts had been made to extract it. The chalk had been partly broken down with the forceps, and there was no space possibly available to pass any instrument behind the mass. I scraped away with a sharp scoop as much as possible of the chalk from the upper wall of the meatus, washing the *débris* away with a syringe. I then persevered in properly directed syringing, and the mass came away under chloroform. Lately, I had a very obstinate case. A child with a smooth stone, rather angular in shape, was

brought to the hospital; the stone was inside the contracted portion of the canal. I tried syringing without avail. The stone, though it was not possible to get any extracting instrument between it and the wall of the meatus, was movable. I determined to wait and syringe. The child was troublesome. Several times, I got him under chloroform and examined the stone with a fine probe and good light carefully. I tried to catch it with cobbler's wax, but it would not come. I made an effort to fit the spoon behind it, but failed. It only went further in. Some inflammation setting in in the meatus, and discharge appearing, I desisted from all efforts, and merely had the ear washed out with warm water daily, filling the meatus each time with glycerine. By degrees, the stone worked its way out, until it was about half way through the narrow part of the canal. I was now tempted to try and get a wire behind it; it only pushed the stone back. I, therefore, determined to do nothing but syringe. Some discharge continued. At the end of three weeks, the stone came away. There was slight catarrh of the passage; but the membrane was not affected, and the child recovered with perfect hearing.

Having thus given the brief details of a few obstinate and difficult cases, I will conclude by quoting these remarks of Hinton and Trötsch on this subject. The former says: "I must be pardoned for speaking earnestly on this point. Even to this day, it remains the fact that ears are thus destroyed without shadow of reason or excuse, and not by careless and incompetent persons alone. I believe it may be laid down as a rule that, whenever an instrument will succeed, syringing would also succeed; and that, when proper syringing will not succeed, all instruments are full of danger; if had recourse to before violence has been used, would probably, in all cases, remove the offending body in ample time to prevent mischief." "Injuries," says Trötsch, "are frequently inflicted on the soft parts of the meatus by patients with itching in the ear by means of knitting-needles or sharp metal ear-picks; graver and more serious frequently prove those contused and lacerated wounds of the meatus, inflicted by a professional hand, in attempting the removal of foreign bodies, even in those cases in which most harmless intruders, as morsels of bread and paper, are concerned. On such occasions, the instrumental foreign bodies are generally the chief part of the evil."

## UNUNITED FRACTURE OF THE FEMUR CURED BY OPERATION.\*

By REGINALD HARRISON, F.R.C.S.Eng.,  
Surgeon to the Royal Infirmary, Liverpool.

A CASE of ununited fracture of the femur, which has recently been under treatment in my ward at the Liverpool Royal Infirmary, presents, I think, sufficient features of interest, if not of novelty, as to render it worthy of record here. In bringing this case under notice, I do not claim any originality in treatment; I have merely applied those principles, although perhaps in a somewhat unusual manner, which are generally recognised in the management of this class of cases.

Austin Zinc, a seaman, aged 26, was admitted into the Infirmary, under my care, on July 26th, 1875. From the patient's history, it appears that, on April 18th previously, whilst at sea, he was struck by the sea in a gale and thrown violently against the side of the ship. It was found that he had sustained a fracture of the thigh. The captain of the ship put a long splint on him, and he was treated as well as circumstances would permit. He was subsequently placed on a steamship for conveyance to England, where he had the benefit of the attendance of the surgeon of the ship, who appears to have done the best to obtain union.

On his arrival in England, on July 23rd, it was found that no union whatever had taken place, and he was consequently transferred to the Infirmary at Liverpool for further treatment.

Upon examination, I had no difficulty in finding a fracture of the femur at about the junction of the upper with the middle third. The fracture was oblique, and the ends were widely separated, the upper fragment being readily felt beneath the skin in front, whilst the lower fragment was deeply embedded amongst the hamstring muscles. There were two inches and three-quarters of shortening. There was no union whatever.

The limb was placed on a splint after friction had been employed, and was kept absolutely at rest for some weeks. Other means were resorted to, including the introduction of a tenotomy-knife to the end of the bone, violent percussion, and friction, but all without avail. No

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

union, or even any sign of reparative action, could be excited. The patient became very weary, and begged to have his limb amputated. On January 4th, 1876, with the assistance of my colleague Mr. Banks, I performed the following operation, the patient being placed under the influence of ether. I made an incision on the outer aspect of the thigh, about six inches in length, and sufficient to enable me to reach the fractured ends of the bone. By means of a small saw and a gouge, I completely bared the lateral aspect of both fragments, each of them to the extent of what they overlapped. After the opposing lateral surfaces of this oblique fracture had been most completely bared, I then passed round both fragments a stout piece of ordinary copper bell-wire, and a second piece at an interval of about an inch and a half. Having placed the wires in their proper relative position, I gradually screwed them up until the bones came into a position similar to that of a splice in a fishing-rod. Having thus screwed up the wires, I had the satisfaction of finding that they held the ends of the fracture in close and firm apposition.

To prevent any slipping, I then passed through the bones, midway between the two wires, by means of an Archimedean drill, a drill-head; this had the effect of completely fastening the two opposing portions of the fracture together. The wound was closed by wire sutures, the other end of the drill-head projecting through the wound. The limb was then placed on an outside interrupted splint, and the patient removed to bed.

Bleeding was entirely controlled during the operation by means of an Esmarch's bandage placed round the groin. The operation was followed by some slight febrile reaction; but, considering the severity of the operation, it was remarkable how little the patient suffered. The chief pain was referred to the position of the drill-head, the slightest touching of which occasioned severe and deeply felt pain. On January 5th, the pain referable to this drill-head was so great that I removed it, fearing that it might set up in the bone an undue amount of inflammatory action. The removal of this was followed by complete comfort. The suppuration was not excessive, and, in the course of a few weeks, the wound was completely filled in with healthy granulation. The wound was not dressed antiseptically. On March 5th, as the wires appeared now to be sources of irritation, I determined to remove them. I had the patient placed under ether. I then passed my finger through the mass of granulations down to the wires, and, by means of a curved pair of cutting pliers, severed and withdrew each wire. This was done without difficulty, and I had the satisfaction of feeling that union was complete. The patient was kept in bed till May 4th, when he was allowed to get up, union being perfectly complete. The amount of shortening was not greater than that observed on his admission; viz., very nearly three inches.

The patient was sent to the Convalescent Hospital at Woolton, where some very small fragments of bone were from time to time exfoliated. On July 10th, 1877, the patient called at the Infirmary to see me. His limb was perfectly firm. He informed me that he had been out to Callao as a seaman, and that he was again leaving on the following day for the same place. Except the shortening, which now appeared to give him little inconvenience, the movements and form of the limb were all that could be desired. The case, in fact, turned out as successfully as I could wish.

In commenting upon it, I would first observe that recourse to operation was not had until it was evident that it was useless to expect union from the employment of rest, position, and other means which are found successful in instances where union is merely delayed. In a seaport like Liverpool, cases of delayed union are not uncommon. Sailors and others are often sent for treatment who have been rolling in ships with fractured limbs, sometimes for weeks; in these, rest and proper treatment are speedily followed by firm union.

In this instance, all ordinary means for securing union had failed, and therefore it was necessary to consider carefully what proceeding offered the best chance of success. It was suggested that a portion of the fractured ends be sawn off, and the case treated as one of compound fracture. This plan, however, did not recommend itself to me, inasmuch as, without some means which would secure apposition and immobility of the fractured ends, it was hardly reasonable to expect union to take place.

As it appeared impossible, under any circumstances, to prevent shortening, I thought it better to avail myself of the overlapping of the fragments, and, by baring the sides of them to this extent, in this way to obtain a much larger bony surface from which union might spring than if section of the ends of the bone were done. For the purpose of holding the fragments thus bared together for a time sufficient to allow union to take place, I determined merely to encircle the bones with wire. I was anxious to avoid retaining the wires in the substance of the bone, as I have seen the plan followed by most violent

inflammation, resulting in extensive necrosis, and thus defeating the object in view. I therefore contented myself with wrapping the wire round the bones.

For the purpose of adding to the security of the union thus effected, and guarding against any slipping of the bones by the spasmodic action of the powerful muscles of the thigh, which is not uncommon for the first two or three days after such an operation, I introduced a drill-head, which firmly "nailed" the fragments together. At the end of four days, I removed this without difficulty, as the pain referred to it became intolerable, and I was fearful of setting up an excessive inflammatory action in the bones; besides, by this time, the drill-head had fulfilled the object I had in view in its introduction. The wires were not removed until union was complete, when, for the first time, Nature began to indicate they were no longer necessary. On their removal, the wound healed kindly, and beyond, from time to time, the throwing off of small necrosed portions of bone, no further inconvenience was experienced by the patient.

The degree of shortening was not greater than three inches, and I was surprised to find how little it interfered with the patient's movements.

I shall not trouble you with any further observations on the case. The treatment of so unfortunate an occurrence as an ununited fracture claims from us all, when opportunity offers, contributions to the literature of the subject.

## DIABETIC COMA: ACETONÆMIA.\*

By BALTHAZAR FOSTER, M.D., F.R.C.P.,

Professor of Medicine in Queen's College; Physician to the General Hospital, Birmingham; Consulting Physician to the West Bromwich Hospital; etc.

THE sudden occurrence of grave symptoms, and death following in a few hours, are startling events in any chronic disease. They are especially startling in a malady like diabetes mellitus, which usually runs a long and comparatively uneventful course. Prout, with his usual keen observation, noted some instances of this sudden ending in diabetes, but has simply referred to them as interesting illustrations of the frail tenure on which the life of a diabetic is held. Later writers have advanced hypothetical notions to account for the phenomena observed in their cases. By some, myself included (*Clinical Medicine*) they have been regarded as uræmic; thickening of the blood to a degree sufficient to render it unfit to circulate, from excessive loss of water, has been suggested by others; the nervous and respiratory systems have been invoked as the centres on which these grave symptoms depend; and, lastly, chemical transformations of the diabetic sugar, leading to the formation of poisonous compounds within the body, have been supposed by some German and Italian authors to be associated with sudden death in diabetes.

There are cases, I have no doubt, to which each of these hypotheses may be justly applied; but my more recent experience strongly inclines me to regard the last mentioned view as the most satisfactory explanation of the hitherto obscure and alarming condition which has been aptly termed diabetic coma. In this communication, I propose to record some cases of this kind, and to inquire how far their clinical aspects support the chemical view.

One morning about twelve months ago, when teaching in the wards, I was called away to see a boy who had been admitted two days before for diabetes. We found the boy in bed, tossing about restlessly, with a very anxious expression of face and slight duskiness of the skin. He had very remarkable dyspnoea. Each inspiration was deep, ample, and chest-filling. Large volumes of air passed in and out of the chest thirty-two times a minute, but seemed to have no power to satisfy the patient's craving for air. On examination, the chest was everywhere resonant, and loud and harsh breathing was heard all over the chest. No odour beyond the ordinary diabetic smell was observed in the boy's breath. The pulse was small and weak, but regular, 136; the tongue was moist, with whitish fur; the temperature in axilla was 97 deg. The boy was somewhat dull mentally, but, when roused, answered correctly. The symptoms had begun the evening before with sickness, which had occurred again early in the morning, and been associated with sharp pain in the epigastric region and rapid breathing. The abdomen

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877; and also before the Birmingham and Midland Counties Branch.

was distended, especially in the epigastric region. When I noted these symptoms, I recognised the beginning of diabetic coma, and expressed to my class the opinion that the case was likely to end fatally in twenty-four hours. An injection to relieve the bowels, which had been confined for two days, an effervescing draught, with half-drachm doses of compound spirits of ammonia every two hours, and brandy in small doses, were ordered. The boy gradually grew worse; the surface grew colder, the face dusker; the rapid breathing lasted for twelve hours, and then grew short and catching; the pulse became feebler and more rapid; the restlessness gave place to coma; the surface became cyanotic; and he died early the next day, less than twenty-four hours after my visit. The urine was passed freely in the bed during the last twenty hours of life.

Now, this boy had been diabetic for more than twelve months, and was admitted to the hospital, not on account of any urgent symptoms, but for the purpose of observing the effect of systematic treatment. On the day of admission, he had come by train ten miles to the hospital, as he was accustomed to do as an out-patient; and, when it was decided that he was to remain as an in-patient, he fretted a good deal, and continued to do so up to the time of the grave symptoms coming on. He was placed on partly restricted diet, and had no medicine, as I wished to estimate the sugar-excretion before beginning specific treatment. He had been passing some 100 to 120 ounces of water daily before admission, with a high specific gravity (1035 to 1038), and containing 2,700 to 3,000 grains of sugar. On the day after admission, the urine fell in quantity and specific gravity (84 ounces, specific gravity 1026), and never rose above 1028 till his death. The sugar was not estimated.

In this boy we had a typical example of the form of sudden death in diabetes, for which we have hitherto lacked any adequate explanation. All who had observed the case, in common with myself, looked forward with great interest to the necropsy, in the hope that it might unravel the mystery.

The *post mortem* examination was made by Dr. Saundby twenty-six hours after death. The brain and membranes were pale and anæmic, and there was no discoverable coarse or microscopic change except hypertrophy of the muscular coat of the arterioles of the pia mater. The lungs and heart were quite healthy; the muscular structure of the heart was pale, but not fatty. The abdomen showed no sign of any inflammatory mischief. The spleen was small and soft. The liver was pale in colour, but normal in structure under the microscope, and weighed 3 lb. 3 oz. A decoction showed the presence of sugar in small quantity. The kidneys were healthy. The stomach showed patchy congestion and catarrh. So far, the search had been fruitless. The blood, however, had not escaped observation. In the brain-sinuses, and throughout the body, it was pale and cream-like. One observer compared it to grumous pus. It was fairly fluid, and did not clot, but, on exposure to the air, became pinker and brighter in colour, assuming a magenta-like tinge. The microscope showed the creamy condition to be due to the presence of a large quantity of molecular matter, which looked like fat, but did not dissolve in ether. There was a small quantity of sugar in the blood.

These appearances were very striking, and pointed to the peculiar blood-change as the one abnormal condition to account for the patient's symptoms. Its nature still remained to be explained. While pondering over this problem, I came on a reference to the ideas of Petters and Kaulich on the development of acetone in the system of diabetics. Acting on this, I at once determined to test the effects of acetone on healthy blood. Dr. Saundby willingly and ably assisted me. We found that, when acetone was added to the blood, it became paler and creamy-looking, presenting the same appearances as the blood of the boy. On exposure to air, the acetone blood assumed after a time the same pinkish red coloration that had been seen in the *post mortem* theatre. Under the microscope, the blood-corpuscles were seen to break down into granular debris, reproducing exactly the state observed in the blood of the patient. Roughly examined, it looked like blood containing a good deal of fat; but neither the artificially acetone blood nor that of the boy owed its appearance to fatty matter. The addition to fresh blood of chloroform, alcohol, or ether, failed to produce similar effects. In these results, then, we had a clue to the explanation of the case. Assuming for a moment that acetone was developed in the boy's system, its destructive effects on the blood would be amply sufficient to account for the great dyspnoea, and the cyanosis, steadily increasing, in spite of the full and frequent inflation of his lungs. The blood-cells were so destroyed that they no longer were able to absorb and fix the oxygen drawn into the air-cells by the vigorous respiratory action of the patient.

Before recording other cases, I propose to sketch very briefly some of

the observations made on this subject by others. Petters (*Prager Vierteljahrsschr.*, 1857) was the first to show that acetone is developed in the system of diabetics, and Kaulich (*Ibid.*, 1860), in confirming this discovery, endeavoured to sketch clinically the state of acetonæmia. This state, he attempted to show, was not peculiar to diabetes, but was also met with in chronic affections of the stomach and digestive organs, and accounted for the depression of the whole nervous system observed in such cases. Betz (*Memorabil. für pract. Aertze*, 1861) followed, referring the presence of acetone in the breath to catarrh of the throat, etc.; and, some years later, Cantani (*Il Morgagni*, 1864; *Syd. Soc. Biennial Retrospect*, 1865-66), endeavoured to show that there were several forms of acetonæmia, occurring mainly in conditions of gastric catarrh. Alcoholic and acetic fermentations of grape-sugar, and possibly of other organic matters in the stomach, was assumed by these authors to be the sources of acetone. The following formula represents acetone:  $C_3H_6O$ . Since then, Bechamp (*Comptes Rendus*, 1872) has shown that alcoholic and acetic fermentations occur in the stomach under favourable conditions, such as catarrh. Rupstein (*Centralblatt für die Medicinischen Wissenschaften*, 1874) believes that the acetone may also be formed in the blood. It has been found there after death, and has also been obtained from the solid organs of a diabetic dying of coma by Berti (*London Medical Record*, September 1874). Acetone is frequently found in the urine of confirmed diabetes, and is often developed in the urine after it is passed; an important fact to bear in mind in estimating the sugar. I have, however, myself detected it in urine immediately after it was passed. I refer last of all to the important paper of Kussmaul (*Deutsches Archiv für Klin. Med.*, Band xiv, 1874),\* who has observed cases of this kind and experimented on animals with acetone. The results of these experiments, which are most interesting, show that acetone is an anæsthetic less potent than ether and chloroform, and acting more like alcohol. It produces great muscular feebleness, quickens the pulse, and causes deep slow breathing, and in large quantities brings on stupefaction. The breath of the animals smelt strongly of acetone. Altogether, the results obtained by Kussmaul's experiments closely resemble the symptoms of diabetic coma. Acetone produces partial anæsthesia, and in large quantities coma. It causes great muscular feebleness generally, but deep and energetic respiratory action. In man, before the coma comes on, there is partial unconsciousness, broken by a happy delirium, in which the patient laughs and jokes when roused, reminding one very much of the effects of alcohol. Summed up, the results so far go to show—

1. That acetone has been found in the breath, urine, blood, etc., of patients who have died of diabetic coma.
2. That grape-sugar may be converted in the stomach by alcoholic and acetic fermentations into acetone.
3. That the changes in the blood observed after death from diabetic coma can be artificially produced by the addition of acetone.
4. That the administration of acetone in large quantities to animals produces similar symptoms to those observed in diabetic coma.

I will now pass on to consider other examples of this interesting affection.

In October last, I was summoned in haste to see a case with Mr. F. Hollinshead of Selly; and, on my arrival, I heard that it was a patient suffering from diabetes who had suddenly got worse, and was rapidly becoming insensible. As we drove to the house, I learned that he had suffered from diabetes some two and a half to three years. He had never lost flesh, but had always been a stout vigorous-looking man, in spite of an excretion of eight quarts of urine daily, of specific gravity 1037. He had been subject to boils, but had usually had no great trouble with them till six months before my visit, when he had suffered from a bad carbuncle on his neck. He recovered from it, however, and regained his usual health, and had been able to perform his daily duties as formerly. About October 10th, signs of another carbuncle showed on the nape; this had increased enormously, and was the beginning of the illness for which I was called to see him. The carbuncle had opened and all had gone on fairly well till forty hours before my visit. His temperature had then risen to 104 deg., and his pulse to 120, while the breathing became a little quick. On the next day, he had a sharp pain in the right hypochondrium, was not sick, but had free eructations of gas, and his breathing quickened somewhat. In the evening (October 24th), he became drowsy and wandered in his talk.

When I saw him on the afternoon of October 25th, I found a man in the prime of life (41) lying in bed on his back, breathing loudly and

\* There is also an excellent account of acetonæmia, with reference to most of the papers on the subject, in Lecorche's *Traité du Diabète*. Paris: 1877.

noisily, but with no stertor. Each inspiration was long, deep, and chest-filling, but seemed to have no influence on the air-hunger; for one rapidly succeeded another, reaching fifty to sixty a minute. His countenance was dusky; his expression was anxious, and there was a good deal of jactitation. The pupils were equal and a little dilated; the pulse small, quick, regular, 150. The hands were cool and moist; the skin moist all over, and perspiration acid. The feet were colder than the hands, and both were dusky in colour. When spoken to, the patient answered, but not to the point, and soon wandered off into a happy kind of delirium. When told, he put his tongue out; it was moist and a little furred. On examination, the lungs were found to be resonant all over the chest, and the air entered freely and fully everywhere. There was a systolic aortic murmur, which he had been known to have for some years. The abdomen was rather tympanitic, but not tender. While I was present, frequent eructations of a gas of peculiar odour occurred. The liver was not much enlarged; the spleen appeared natural in size; the bowels had acted well, but the quantity of urine had decreased during the last twenty-eight hours. The temperature in the axilla was 104 deg. Fahr. The patient got out of bed in my presence and passed urine (about a pint); but he was greatly exhausted by the effort; his muscular strength was almost gone, and there was partial anæsthesia of the limbs.

This man's breath had a most peculiar odour, which reminded me strongly of a case seen some years ago. It was strongly impregnated with acetone. I asked one lady who was with the patient, and who had visited him from time to time during the day, if she had applied any vinegar-cloths to the patient's head. I asked this question with a purpose. She answered: "No; but I thought the nurse had; for, when I came in this morning, the room smelled of stale vinegar"; but she added: "The smell comes from his breath." So it was; the room was saturated with this vinegar-like smell, likened very aptly by Mr. Hollinshead to that of stale beer. So strong was it, that it gave all who stopped long in the room headache and slight drowsiness. The smell was unmistakable; every expiration, and every eructation of gas from his stomach, poured forth volumes of acetone, thus freely volatilised, on account of the high temperature of the patient.

Drowsiness and coma gradually superseded the delirium, the patient grew quieter and more comatose, the breathing became less vigorous and more broken, the muscular feebleness and anæsthesia increased, and he died insensible seven hours after my visit. For this end, we were prepared; the case was a hopeless one; acetonæmia killed him, in spite of any remedies we could administer.

The urine had fallen in quantity, as it does in most instances of this kind; the sugar also is usually lessened, from the fact of its conversion in the system into acetone. The urine I obtained had only twenty grains of sugar per ounce, a much less quantity than he had formerly passed most probably, and showed a distinct reaction with the acetone test. The blood of this patient I should have very much liked to examine; but my colleague Mr. Hollinshead was unable to procure any for me, or to obtain a *post mortem* examination. If we had been able to procure a specimen of the blood, we should, I have no doubt, have found the same disorganisation of blood-corpuscles that I have described in the former case. In such a condition, we have an explanation of the coincidence of the deep vigorous breathing and the general cyanosis of the surface: a duskianness worthy of death by asphyxia, associated with full and frequent inflation of the lungs.

The attempt was made in this case to arrest the disorder by remedies. Carbolic acid and sulphurous acids were administered in water as drinks; but the case ended too quickly to be of any value as a test of the treatment.

Must this fatal ending always occur when symptoms of poisoning by acetone once arise in a diabetic patient? I think not. Many milder cases pass unnoticed, and, in many instances, the slighter effects of acetone are put down to temporary brain-disturbance, and no more account is taken of them. In other instances, symptoms less grave than those I have described, but yet sufficiently serious to cause considerable danger to the patient, result from acetonæmia; but the process is arrested either naturally or by treatment, and the life is saved. A very striking example of this kind I saw not long since with Mr. George Jones of this town.

The patient was a gentleman aged 64, who had suffered from diabetes for upwards of two years, but had greatly improved under opium treatment. About a week before I saw him, he had become affected with bronchial and gastric catarrh. The attack had been preceded by a good deal of mental worry, which had lowered his state of health. The chest-troubles had decreased; but his breathing had confined it to rapid, his temperature high (101½ deg. Fahr.), and drowsiness and delirium, with a pulse intermitting every third beat, were the conditions which led to a consultation. I found a strong-looking man

in bed breathing thirty a minute, drowsy and restlessly excited by turns. He wandered at times like a man in drink, and was cheerful and good-humoured in his fancies. The pupils were equal and a little dilated. There were slight dulness and coarse moist sounds at the right lung-base, but the air entered all the rest of the chest freely. There was tenderness over the liver, which was full in size. The abdomen was rather distended by gas; the tongue was moist but loaded; the breath had a faint smell of acetone; the urine, which was not measured for the twenty-four hours, was 1034 specific gravity, contained twenty-five grains of sugar per ounce, and gave a distinct reaction with test for acetone. Suitable remedies were prescribed for the heart and lung-conditions, and, on the third day, when I again saw him, they had greatly improved. The pulse was again regular, 108; the temperature was 99½ deg. Fahr.; the physical signs at the back of the chest were almost gone, but the breathing, though slower, was very deep and almost sighing in its character, and the head-symptoms had decidedly increased. The patient was more frequently unconscious; he could be roused; but, when left alone, he wandered more in his talk, being very restless and excited. This state had lasted twenty-four hours, and was associated with alarming muscular feebleness. He had passed only eighty ounces of urine in the twenty-four hours; it contained thirty-one grains of sugar per ounce, and showed more distinctly than the last the presence of acetone. The breath also was more decidedly impregnated with acetone. The tongue was dry and red. My colleague took, with me, a grave view of the case, and we decided to alter the treatment by giving carbolic acid in a drink, so that the patient could take two grains every hour at first, and then every two hours. We gave opium also in larger doses, as Mr. Jones had convinced himself that it possessed to a high degree in this case the power of checking the formation of sugar. By this, we hoped to lessen the amount of diabetic sugar formed, while by the carbolic acid we trusted to prevent the conversion of the sugar that was formed into acetone. The next day, the patient had improved; the nervous symptoms were all less marked, and, on the second and third days, he had improved still more. After this, he took the opium alone, and, when I saw him on the tenth day, on account of a new complication, in the shape of an aphthous condition of the mouth and pharynx, the symptoms of acetone-poisoning had all passed away; his breath had still a faint odour of it, and the urine gave a slight reaction. After this, he made a good recovery, and, when I last examined his urine, it was free from acetone, and contained only nine grains of sugar per ounce.

The above cases, in addition to others which I have seen, have led me to conclude that we have in the acetonæmia hypothesis the best explanation of diabetic coma. Patients who are seriously diabetic have, in all probability, a small quantity of acetone constantly formed in their economy. It is this which gives the odour to the breath and to the urine. It would appear that, under conditions of nervous depression and exhaustion, and more especially conditions favouring stomach-catarrh, the quantity of acetone formed may rapidly undergo great increase and give rise to the acute symptoms which lead to sudden death; a chronic poisoning, as Kussmaul remarks, suddenly taking on an acute form, like delirium tremens in habitual drinkers. The similarity in the symptoms of some of these cases to the effects of alcohol make it highly probable that alcohol is also formed in the system. I find that Senator, in his valuable treatise on Diabetes in *Ziemssen's Cyclopaedia of Practical Medicine*, vol. 16, also holds this opinion.

In the discussion which followed the reading of this paper at Manchester, the difficulty was raised that, in some of these cases, there is no smell of acetone in the breath. This is so. In the first case here recorded, there was no marked odour. This is to be accounted for by the fact that acetone requires a high temperature for free volatilisation. In some experiments recently made, I find that from urine, for example, very little acetone is given off till the temperature reaches 100 deg. Fahr.; but, above this point, it is given off quickly. The cases in which I have observed the smell of acetone most distinctly have been cases with high temperatures, as in the second case in this paper. The temperature of diabetics is not, as a rule, high enough to send it off in any quantity.

Finally, if the explanation of diabetic coma here supported be the true one, we may look forward to more precision in its treatment. Transfusion has failed in this country and abroad; the inhalation of oxygen has been tried in vain; elimination of the poison by ordinary methods can hardly be trusted in these sudden attacks; I therefore used carbolic acid in two cases narrated, in the hope of checking the fermentative process which develops the poison. So far as it goes, the history of one case supports the practice. Salicylic acid and its salts

are remedies also worth trying on this view, and especially thymol, which has been suggested to me by Dr. Burdon Sanderson as a more powerful and pleasant agent of the same class. The remedy will not long be wanting when the morbid process is fully understood.

## BATH THERMAL MINERAL WATERS: THEIR USES AND ABUSES.

By A. B. BRABAZON, M.D.,  
Physician to Bath Mineral Water Hospital.

NOTWITHSTANDING the title with which I have prefixed the purely practical remarks which I am about to offer to the readers of the JOURNAL, I fear some may consider the subject a dry one.

In many aspects, the subject has been well nigh worn out; and the deservedly highly extolled natural beauties of Bath, its environs, its antiquities and its salubrious climate, its fauna and flora, have all been eloquently described in language which I dare not and could not emulate. The task which I have set before me is one which, both for writer and reader, is bereft of all such charms and devoid of all such interest. My object is purely practical, as will be my observations; and in this sense alone do I venture to place them before my professional brethren, for the following reasons.

1. Because I am not aware of any attempt, founded on statistical information combined with personal experience, to classify, arrange, or tabulate, in any systematic form, the effect of the Bath mineral waters on the patients submitted to treatment therewith, either as regards age or sex, whether in hospital or in private practice.

2. I feel assured that the want of some such information must occasionally, and indeed frequently, be felt by my professional brethren, living, possibly, at a great distance from Bath, when called upon to decide, in any given case, whether the chances of cure or improvement are such as to render it advisable for the patient to undertake, possibly, a long and tedious journey.

3. I know, from personal observation, and I think my colleagues in connection with the Bath Mineral Water Hospital will bear me out in the statement, that the want of some such information is occasionally made painfully apparent in the character of the recommendation of candidates for admission to hospital, which are submitted to the medical staff. Moreover, it is not only in hospital cases that one finds such want of correct ideas as to the therapeutical powers of the waters displayed, but also, and probably more frequently, in private practice. I have, in my own experience of sixteen years, frequently met with patients sent to Bath. I might say to die, to whom the long journey must have been a cruel and painful infliction, and to whom even alleviation of their sufferings was almost an impossibility, unless the Bath waters were a veritable "Pool of Siloam". Such are the cases, fortunately rare, which bring such bitter disappointment to those concerned, and are calculated to cast doubt and discredit on the efficacy of these mineral waters, which are, I confidently believe, second to none in their curative powers in cases suitable for their administration.

In making this humble attempt to arrive at even something like definite conclusions on the subject in hand, I must beg my professional brethren to remember that the conditions under which such an attempt is made differ widely from those which obtain in reporting or relating circumstances connected with the history of disease otherwise treated. The cases on which are founded any observations, statistical or practical, which I may venture to offer, are, as a rule, subacute or chronic in their character. There are no hourly or daily changes to be reported; no frequent variations of pulse, temperature, or even treatment, to excite any special interest. The process, by which alone we can arrive at anything approaching to definite conclusions is the tedious and comparatively uninteresting one of observation, not of individual, but of aggregate cases of disease, as they are presented to our view in hospital or private practice. Thus, it becomes necessary to arrange, in some tabulated or statistical form, those cases from which we wish to derive therapeutic information of any scientific or practical value.

1. I propose to tabulate, under certain heads, the diseases which have been treated in the Bath Mineral Water Hospital during the past three years.

2. I shall append statistical tables representing the results of treatment in these various forms of disease as to sex and age, and giving the percentage as regards results: first, respecting sex; secondly, respecting age—these percentages being averaged on a given number of patients discharged from hospital within the several periods of life recorded.

3. I shall endeavour, as far as possible, from hospital statistics and from general observation, to delineate these diseases, in their general

aspect as well as in their particular forms, which positively or comparatively are successfully treated by the use of the Bath mineral waters, whether used internally, or applied externally, or administered in both ways.

I may here mention that, although the general rule adopted in almost all health-resorts famous for mineral springs—viz., that of restraining patients from taking any kind of medicine while making use of the water—is followed, yet, under certain circumstances, the most experienced physicians in Bath do not hesitate to supplement the waters with additional therapeutical means when they consider it judicious to do so. On the present occasion, it is impossible for me to individualise those cases so treated, but at some future time I may be able to do so. At present, I can only, in my observations, allude generally to those cases in which my individual experience would lead me to adopt some such supplemental treatment.

The diseases admitted or admissible into the Bath Mineral Water Hospital may be divided, for convenience of description, into four classes.

1. *Constitutional Diseases*; 2. *Local Diseases*; 3. *Diseases from Specific Causes*; 4. *Miscellaneous Diseases*. These four classes will include, each respectively, certain subclassifications, which I shall tabulate as follows.

1. *Constitutional Diseases*, producing local or general effects: A. Rheumatism (including muscular, articular, and chronic rheumatic arthritis); B. Gout (pure and so-called rheumatic gout); C. Sciatica (gouty, rheumatic); D. Lumbago (gouty, rheumatic); E. Coxalgia (gouty, rheumatic, or arthritic).

2. *Local Diseases*, with or without constitutional causes: a. Hemiplegia; b. Paraplegia; c. Chorea; d. Neuralgia; e. Paralysis after Injury; f. Hysteria (simple and complicated); g. Wasting Palsy; h. Locomotor Ataxy; i. Skin-Diseases (including eczema, lepra, psoriasis, impetigo, acne).

3. *Diseases from Specific Causes*, such as effects of metallic poisoning, including dropped wrist, colica Pictonum, mercurial poisoning.

4. *Miscellaneous*: Amenorrhœa, dysmenorrhœa, anæmia, debility, and others of various types which occasionally crop up among patients who may have been admitted for other forms of the diseases above mentioned.

The results of treatment I have divided under four different heads: 1. *Cured*; 2. *Much Better*; 3. *Better*; 4. *No Better*. As this classification may be considered somewhat arbitrary, I must beg leave to explain that, according to a time-honoured custom, all patients discharged from the hospital are discharged under one of the above-named divisions. I shall, as far as possible, define the meaning to be attached to these four terms or divisions. Under the head of "Cured", I include all those patients who leave the hospital free from all symptoms (constitutional or local) of the disease for which they have been admitted, and who are discharged able to follow their special trades or avocations. Under the head of "Much Better", I include all those patients who have obtained relief from pain and other prominent symptoms, and who are most of them sufficiently recovered to return to their usual occupations. Patients discharged as "Better" I may describe as simply temporarily relieved of their most painful and prominent symptoms. Under the head of "No Better", I comprise all cases in which, after sufficient trial, the mineral waters, however administered or supplemented, have been perfectly inefficacious.

I shall take the several diseases enumerated above into consideration in order, commencing with that of which the greatest number has passed out of hospital—viz., rheumatism in its various types and kinds.

During the year ending May 1877, I find 415 cases of rheumatism were discharged from hospital: that number being composed of 260 males and 146 females. Distributed according to periods of life, I find the following results:

	Males.	Females.	Total.
Under 20 .. .. .	23 .. ..	24 .. ..	47
20 to 40 .. .. .	111 .. ..	69 .. ..	180
40 to 60 .. .. .	107 .. ..	43 .. ..	150
Over 60 .. .. .	23 .. ..	10 .. ..	33
	269	146	415

In explanation of the appended tables, I beg to state that Table I gives the results of treatment under four divisions, as above described, and within four periods of life; it also gives the total of males and females regarding these separate results of treatment, according to ages above mentioned.

Table II gives the percentage of results of treatment in proportion to numbers discharged under ages mentioned and according to sexes. As an illustration, under 20 years, 13 cases (males) were cured; total number of males discharged under 20 = 23; therefore, the percentage

of males cured under 20, in proportion to total number of males discharged at same age = 56.5.

TABLE I.—Cases Discharged.

Result.	MALES.				FEMALES.				Total Males.	Total Females.	Total Both Sexes.
	Under 20.	From 20 to 40.	From 40 to 60.	Over 60.	Under 20.	From 20 to 40.	From 40 to 60.	Over 60.			
Cured.....	13	34	18	4	8	8	6	0	69	22	91
Much better..	10	67	74	14	13	50	23	8	165	94	259
Better.....	..	9	10	6	3	8	11	1	23	23	46
No better....	..	1	5	4	..	3	3	1	10	7	17
Total ....	23	111	107	28	24	69	43	10	269	146	415

Table III gives also the percentage of results as affecting both sexes separately and collectively, according to total discharged.

TABLE II.—Percentage of Cases Relieved, etc.

Result.	MALES.				FEMALES.			
	Under 20.	From 20 to 40.	From 40 to 60.	Over 60.	Under 20.	From 20 to 40.	From 40 to 60.	Over 60.
Cured.....	56.5	30.6	16.8	14.2	33.3	11.5	13.9	..
Much better..	43.4	60.7	69.1	50.	54.1	72.4	53.5	80
Better.....	..	8.1	9.3	21.4	12.5	11.5	25.5	10
No better....	..	..	4.6	14.2	..	4.3	6.9	10

TABLE III.—General Percentages.

	Total Males.	Total Females.	Total both Sexes.
Cured ..	29.7	15.6	21.9
Much better ..	61.3	64.3	62.4
Better ..	9.7	15.7	11.5
No better ..	3.7	4.7	4.9

I trust the explanation I have given will enable my readers to follow me through the following analyses of results.

First, as to those discharged "cured": among males, the percentage falls regularly with increasing age; among females, the percentage becomes lower, but not in regular gradation, as we find the percentage of those discharged cured is higher between 40 and 60 than between 20 and 40. It is not easy to explain this apparent anomaly; had the ages been divided into decades, the cause might have been more apparent, and would probably be found to exist in the fact that between 20 and 40 is the childbearing age, bringing with it all the anxieties of domestic life, and rendering the sufferer much less amenable to treatment and much more difficult of cure than those of the male sex at the same age. The percentage of cures under twenty is, both male and female, proportionately to other ages, very large, 56.6 for males and 33.3 for females; doubtless, at this period of life, disease has had less time to stamp the patient with irretrievable consequences, and, moreover, very many of the cases admitted under twenty are suffering from effects of acute rheumatism, and are certainly more favourable cases for treatment as regards a prospect of cure than cases more advanced in age and more chronic in their character. The total percentage of cases among males in proportion to total number of males discharged is largely in favour of the sterner sex, amounting in males to 29.7, and in females to 15.6; in other words, the number of cures effected in males as compared with females is nearly two to one per cent.

The average of cures per cent. in both sexes collectively (21.9) is, I think, sufficiently large to demand attention; and I should think, if compared with the results of treatment of similar institutions either at home or abroad, were such a proceeding possible, would be found as favourable as could be truthfully represented.

I next come to the averages per cent. of those discharged "much better"; and I beg of my readers to attach to this term a value neither more nor less than that contained in the definition already given: 259 patients out of a total of 415 were discharged under this term, 165 males and 94 females. The percentage under this head is in favour of the females in the proportion of 61.3 to 64.3. The females have the higher percentage under twenty, from twenty to forty, and also over sixty. Males have the advantage at the period between forty and sixty. I would explain these averages in this way. Females, happily, in our country, are objects socially of great care and attention, and,

accordingly, girls under twenty are probably more objects of solicitude and anxiety, and less exposed to climatic influences, than lads of the same age, and their complaints are sooner attended to. Between twenty and forty, for a somewhat similar reason, females have the benefit of treatment sooner than the bread-winners of the family, who, at this period of life, can least afford, and are most unwilling, to succumb to effects of disease; but after forty comes the grand climacteric of female life, with all its constitutional disturbances and eccentricities. No wonder if we find, then, all treatment of disease comparatively ineffectual. The number of both males and females discharged over sixty as "much better" (only 22) are too few to enable us to arrive at a definite conclusion; as it stands, the percentage is in favour of the females in the proportion of 80 to 50 per cent.

I now come to those patients discharged under the category of "better". I confess, knowing the elasticity of that term, I feel much less disposed to place implicit reliance upon any conclusion arrived at under this head than on those arrived at under the other three heads. Many may be considered as very little more than "no better", indeed, a considerable number almost inappreciably so. The numbers discharged thus are comparatively small—25 males and 23 females, making a total of 48; here, again, the percentage is in favour of the females in the proportion of 15.7 to 9.7.

Last and lowest in numbers, but far from least in importance, I come to the consideration of those patients discharged "no better". The total number discharged thus, according to the records of 1876-77, amounts to but 17, composed of 10 males and 7 females; but I cannot help thinking that this number might receive a considerable addition from those described under the previous head. The hospital physicians are compelled, to a considerable extent, to accept the statements of patients, on being discharged, as to their actual condition; and, doubtless, many patients, from a feeling of thankfulness and gratitude for kind treatment in hospital, declare themselves better, who might more strictly speaking be relegated to the ranks of the "unfortunates". Moreover, I may say there are very few patients indeed who do not leave the hospital much improved in their general condition, though not improved as regards their specific ailment, and who gladly, on this ground, pronounce themselves better. However, I can, from personal observation, positively affirm that the number discharged "no better" is insignificant in the extreme. Analysis of the statistics shows that, under twenty, there were no patients discharged as "no better", either male or female. Out of 111 male patients discharged at ages between twenty and forty, one was no better; out of 69 females discharged within the same periods, three were discharged in the same condition. Out of 107 male patients discharged between forty and sixty, five were "no better"; 43 females were discharged within the same periods, and three were in a similar condition. Twenty-eight males were discharged over sixty; four received no benefit. Of ten females within similar periods, one was no better. The percentage between twenty and forty is much more unfavourable among females than males, being in the former sex 4.3, in the latter .9. From forty to sixty, the average is in favour of the males in the proportion of 4.6 males to 6.9 among females. Over sixty, the fair sex have it all in their favour, as the female percentage of "no better" is only 10 against 14.2 on the male side. I think the above percentages are only what we might expect. Up to sixty, the weakness of sex in resisting the effects of such a disease as rheumatism in its varied forms is palpable, and consequently females are less amenable to treatment than males; but after sixty the effects of the "battle of life", in addition to the consequences of disease, produce more hopeless cases among males than females. On the whole, the male average presents a more favourable aspect, though slightly so, than that of females, standing as 3.7 against 4.7. The total percentage of those "no better" in the combined sexes is 4.9, very low indeed.

I have now arrived at what may be called the summing up of the statistical evidence as to the efficacy of the Bath mineral waters in the class of disease under consideration. I know that evidence of this description, devoid of records of accredited clinical observation, may, by some severely critical members of the profession, be considered useless or even derogatory in a scientific point of view. No one knows better than myself that, as regards science, it may not be of much utility; but I fully believe that, as far as regards the practical object which I have in view, it will be found of considerable advantage. I have simply recorded results of diseases diagnosed by the hospital physicians, and I cannot think that there can be much doubt in such diagnosis, as there cannot have been much difficulty.

I think the foregoing statistics of the results of treatment as to age and sex will sufficiently point out those cases which may be considered favourable or unfavourable. I will venture, however, to make some remarks, as the result of my own personal observation, extending over a considerable period of time.

In estimating the probable amount of benefit or improvement likely to be derived from the use of the Bath mineral waters in any given case of rheumatism, at least two conditions must be considered, independently of age or sex: first, of *complications*; secondly, *conditions of parts affected locally*.

As to *complications*, those of the head and chest are the most likely to arise. I only give my own private opinion on these conditions. I have an unfavourable opinion of this form of mineral water treatment in cerebral complications suggestive of organic disease, whether it be in rheumatism or any of the diseases usually submitted to such treatment. As regards functional disturbances, such as are frequently produced by rheumatic poison—*e.g.*, headache, vertigo, visual affections, etc.—I believe that they form no bar to the use of the waters, carefully applied, internally or externally. I have in my own private practice, and also in hospital cases, met instances of rheumatism affecting the membranes of the brain, frequently preceded by rheumatism of the scalp, which were permanently relieved by the mineral water treatment. In such cases, the diagnosis is occasionally obscure.

In chest-complications, as we would expect, those of the heart are by far the most frequent. Here, again, the existence of organic or functional disease makes all the difference. Rheumatic poison, as we all know, produces functional cardiac affections generally of the anemic type; but I have generally found the internal use of the waters, occasionally supplemented by tonic treatment, produce the desired effect. In organic cardiac affections complicating rheumatism, I consider serious questions may arise as to the advisability of such treatment. In a case of decided fatty degeneration, I should certainly not advise baths. In cases of valvular disease, much would depend on the age of the patient. Were he or she over sixty, I might advise the internal use of the waters, but not the baths. I am speaking, of course, of the treatment of the rheumatic, not of the cardiac, affection. Under forty, and certainly under twenty, I do not think the existence of valvular disease need absolutely prevent the careful and judicious administration of the waters sufficiently far to alleviate pain and other symptoms in chronic rheumatism; but I must be understood to say that much depends on degree as to the valvular affection.

As to pulmonary complications, those most frequently met with in rheumatism are bronchitis, asthma, and phthisis. Bronchitis does not appear to me to be so frequently a complication of rheumatism as of gout; nor do I think that the existence of chronic bronchitis predicates the probable inutility of the mineral waters in a given case; neither does the existence of spasmodic asthma. As a rule, the complication with cardiac asthma is, I think, very generally highly unfavourable; but this is scarcely a pulmonary complication. Pulmonary tubercular complications of every kind, and at every stage, I have, in my own experience, found, as a rule, fatal to beneficial results from the use of the waters. There may be exceptions to the rule, but I have not met with them. I can recall to my memory at least three cases in private practice, all females, who came a long distance to Bath for the benefit of the waters, each crippled with rheumatism, having softened tubercle in the lung and constitutional symptoms of advanced disease. Even the occasional use of the baths increased the local lung-irritation, and also as surely aggravated the constitutional symptoms. They had much better have remained at home, and been spared the trial and consequent disappointment of the effect of the mineral waters.\*

I now come to prognosis as depending upon local conditions. I think I may assert that muscular rheumatism, independent of articular affections, is the form most favourable for the exhibition of the Bath mineral waters, both internally and externally. I have already pointed out from statistics that cases under twenty are in large proportion, and probably most cases of simple muscular rheumatism are to be met with under that age or under thirty; but, even at much more advanced age, muscular rheumatism, if not entirely curable, is certainly affected by treatment so far as to be made much better. As to articular rheumatism, one must speak much less decidedly. Much depends on the conditions inside and outside the joint affected. True ankylosis (osseous), I believe, scarcely ever exists as a result of rheumatism; but fibrous ankylosis of long standing, particularly if accompanied by thickening of the capsule and loss of all movement of the tendons, connected with flexion, extension, or other movements of the joint, produces results almost quite as unfavourable for treatment by baths as complete ankylosis. The best guide in prognosis in such cases is to take into account, first, the age of the patient; secondly, the duration of the comparative immobility of the joint; thirdly, the amount of mobility which may be effected by the hands of the examiner. The position in which the joint has been allowed to become ankylosed forms also an

important ingredient in the prospects of improvement. I may here mention that a perusal of Mr. Brodhurst's work has firmly impressed me with the idea that there are numerous cases in which surgical interference, supplemented by the use of mineral baths, would be successful in restoring to joints a favourable position and sufficiently useful motion to make an useful joint.

I think my readers will fully understand from the foregoing remarks the conditions which will probably render a cure or even improvement likely to take place in any given case of arthritic rheumatism. Chronic rheumatic arthritis, once developed as a fact, is, as we all well know, a form of disease in which cure is hopeless. I mean when it has arrived at that stage in which there are "eburnation of the cartilages" and locking of the joints by osseous or fibrous deposits around the head of the bone, or rather around the circumference of the joint, if it be an enothrardial joint, as the hip. Nothing can restore the destroyed cartilages or the synovial membrane. Nevertheless, pain may be relieved, and even some slightly increased motion imparted; or, if the disease be recognised and submitted to treatment in its early stages, much may be done to prevent pathological results; and I believe that no therapeutical agents will be found more effectual in promoting this most desirable object than the timely use of thermal mineral waters, such as are to be found in Bath. I have delayed, I fear, too long on the subject of rheumatism; but many remarks which I have made will be equally applicable to other diseases usually treated by the Bath mineral waters, my remarks on which I hope I may be permitted to lay before the readers of the BRITISH MEDICAL JOURNAL on a future occasion.

[To be concluded.]

## CLINICAL OBSERVATIONS ON MACULE ATROPHICÆ.

By ROBERT LIVEING, M.D., F.R.C.P.,

Lecturer on Dermatology in the Middlesex Hospital Medical School.

STRIÆ atrophicæ or linear atrophy is a fairly common affection, and usually takes the form of white stripes or bands from one to several inches in length and about half an inch or more in width, tapering towards each end. They occur in groups, especially about the hips and thighs, and are arranged in more or less parallel curves. Their colour is peculiar, and of a glistening bluish white, resembling mother-of-pearl. The atrophied condition of the skin is more easily felt than seen; to the touch, these streaks appear like furrows depressed below the surface, while the tissues over them seem tense, dry and thin. Microscopical examination shows that this is really the case, for there is a complete atrophy of the papillary layer of the skin, and a great diminution in the vascular and fatty tissues of the part affected.

The *macular* variety of this disease is far more rare than the striated form, but it is of exactly the same nature, and presents greater facilities for studying the different stages of the disease. I have lately had under my observation a patient suffering from macule atrophicæ, in whom the period of its duration had extended over six or seven years, and who exhibited a large number of spots in all stages of progress and of ages varying from a few weeks to several years, so that I was well able to observe the disease in its different phases of development. In the case to which I refer, the eruption affected the skin about the upper edge of the sternum, and extended up the neck nearly as high as the cricoid cartilage. It had been developing slowly for several years, fresh spots appearing from time to time, and going through a regular series of changes, which could all be seen and studied at the same time in the same individual.

The *first* stage, which I do not find described by authors, is one which is characterised by slight redness and by well marked hypertrophy rather than atrophy, for the spots are raised above the skin and are hard and fibrous; this enlargement is soon followed by an atrophic change, and we have produced the white appearance which is so characteristic of the *second* stage of the disease. The atrophy at this period is easily seen and more easily felt: on pressing a spot with the finger, the sensation is produced of touching a pit-like scar covered by a thin membrane. The size of the largest spots in the case mentioned did not exceed a threepenny-piece, and most of them were much smaller; they were all discrete and more or less round or oval. The general effect produced by macule atrophicæ is very striking and quite unlike that of any other affection. This is due chiefly to the abrupt contrast in colour between the opaque bluish white spots and the surrounding healthy skin. Another point of interest that I was able to observe, in addition to that already mentioned, was a *third* or *final* stage, consisting in the obliteration of some of the oldest

\* I have not yet had sufficient experience of the results in Bright's disease to enable me to form a decided opinion.

spots; I cannot say that this obliteration was quite complete, because it was possible, by a close inspection, to see where they had been. They had much shrunk in size, and this shrinking appeared to me to be produced by a kind of lateral compression, as if the surrounding healthy tissues had encroached upon the spots so that they ceased to be a disfigurement. Thus we really have three distinct stages in this curious and rare disease; first, a hypertrophic stage, which is well marked; secondly, an atrophic stage, which is the only one usually described; and thirdly, a stage of contraction or obliteration.

A very interesting question arises as to the nature of these maculæ atrophicæ. Kaposi places them among the partial idiopathic atrophies of the cutis, and seems to overlook altogether the early stage of the disease that I have here described. We have no more right to regard them as simple atrophies of the cutis than we have so to regard many forms of scleroderma, unless it be contended that as atrophy is only occasional in scleroderma, and invariable (if it be so) in striæ and maculæ atrophicæ, therefore they may with more propriety be regarded as local idiopathic atrophies. Be that as it may, there is a hypertrophic stage, which I have described above, and which precedes any atrophic change whatever, and leads one to look upon this disease as closely allied to scleroderma. This view is confirmed by the fact that striæ atrophicæ have been observed in several instances coincidentally with morphea and scleriosis.

### THE POSITION OF REST IN FATIGUE AND IN PAIN.\*

By THOMAS S. ELLIS, M.R.C.S. Eng.,  
Surgeon to the Eye Institution, Gloucester.

THE importance will readily be acknowledged of everything which helps to define the principles on which *rest*—physiological or mechanical—should be applied to the treatment of disease.

Passing by other points (for instance, the discrimination between inactivity too prolonged or too complete, and necessary or desirable rest), it has seemed to me that, as this latter can in many cases be obtained only by completely fixing limbs for the time in one position, it is worthy of inquiry—What is *the* position in which the various parts of the body are most at rest? and, What are the laws which determine it?

It may, I think, be laid down as a rule that the position which limbs assume, when from any cause in pain, is essentially the same as that which is sooner or later assumed when in a state of rest from fatigue.

A man may "stretch his wearied limbs" for a short time, but he never retains them for long in a stretched position; by-and-bye they are drawn into one similar to that assumed when in pain, as a rule immediately on the pain accruing; for although, on a blow being struck over a muscle, the first movement may be to put that muscle in a state of relaxation, this is temporary only. Sooner or later, a limb in pain, as in fatigue, seeks what I call the *position of rest*—more marked in joint-disease, and especially in disease of the hip, but essentially the same. Briefly, it may be said that the arm falls to the side, the forearm is flexed and pronated, the hand in a line with it, and the fingers bent, but the index and thumb less so than the others; the thigh is flexed and rotated inwards, the knee bent, the foot tending towards the line of the leg, the great toe a little extended, the others rather contracted; and these rules hold good for parts of limbs left after amputation, at whatever point divided.

It has appeared to me probable that these constant positions, set up on the operation of different exciting causes, would have an explanation common to all. None that I know of has been given, as far as relates to pain generally, or to fatigue; but Mr. Hilton thus explains why an inflamed joint is flexed: "That the irritated or inflamed condition of the interior of the joint, involving the whole of the *articular nerves*, excites a corresponding condition of irritation in the same nervous trunks which supply both sets of muscles, extensors and flexors; but that the flexors, by virtue of their superior strength, compel the limb to obey them, and so force the joint into its flexed condition." (*Rest and Pain*, page 150.) Further on (page 157), he explains an exception in the case of the wrist, which when inflamed is straight, "in consequence of the flexing and extending forces being pretty equally balanced". So also the relatively less flexion of the thumb and forefinger, when the joints are inflamed, as compared to the other fingers. But this, even if otherwise satisfactory, involves no explanation of the position, when assumed as a consequence of pain from causes other than joint disease, or as a relief to fatigue; and I presume to offer an opinion that the real explanation of *all* is simply this:

That the limbs seek a position in which the parts of them are in a state of least tension and of least pressure; as skin and muscle have a property of ready adjustment, while ligaments have not, so, to obtain this, which I call the position of rest, it is necessary that the joints should be in such position that none of the ligaments are on the stretch, that is, somewhere about a mean between the ranges of easy motion.

This, then, I believe to be the principal element in determining the position of rest, though no doubt it is essential, too, that the articular surfaces should be in the position best adapted for each other. To me it is a readier explanation of the difference between the wrist and the elbow or knee; the wrist allows flexion and extension beyond the straight line; the position of rest, therefore, is neither, or straight: while the elbow and knee range in motion between extreme flexion and the straight line; the position of rest, therefore, is moderate flexion. It accords, too, with my statement that the position, essentially the same as in pain from other causes and in fatigue, is more marked in joint-disease.

To object, as I have heard done, that the ligaments are not sensitive, seems to me like arguing that to pull the hair of the scalp cannot cause irritation, because hair has no sensibility. Tension of any structure is never long tolerated.

Mr. Hilton (*op. cit.*, page 150) lays great stress upon the anatomical fact that "*The same trunks of nerves, whose branches supply the groups of muscles moving a joint, furnish also a distribution of nerves to the skin over the insertions of the same muscles; and, what at this moment more especially merits our attention, the interior of the joint receives its nerves from the same source.*" On this he remarks: "This implies an accurate and consensuous physiological harmony in these various co-operating structures." Exactly so, but this is just what I insist on; the muscles, as the motor agency—some contracting, some relaxing—put the limb in a state of rest, a state of the least tension, which I would suggest as more like an "accurate consensuous physiological harmony between co-operating structures" than would be the excitement of an unequal contest between flexor and extensor muscles, leading to the inevitable victory of the one, and inducing a position which, Mr. Hilton says, ought at once to be changed. I am referring to the first passage I quoted (*ante*) and also to page 155, where he lays it down, as seeming to him, "that it is a great mistake on the part of professional men, when they see an inflamed knee or other joint beginning to be contracted or flexed, not to correct it at once".

On page 153, the "mischievous assiduity" of the flexors is spoken of; and again (page 152): "The muscles, indeed, appear to be told, through the medium of the nerves of the interior of the joint, that its articular surfaces are overtaxed; and, the antagonistic muscular forces of the joint being involuntarily excited, the joint is at once rendered rigid and stiff, for the purpose of keeping it at rest."

Let us now inquire what is the effect of irritation of a portion of skin upon muscles which are supplied by nerves from the same trunk as those supplying the skin. The musculo-spiral, which is an example given by Mr. Hilton, is a good test. Let the outside of the forearm be bitten by a dog, or torn, or burnt: does the injury excite contraction of the supinator-extensor group of muscles which are alone supplied from the same nerve? Do we see patients, under such circumstances, with the arm in any other position than that which I call the position of rest? I think not. I can understand this on the principle of "harmony between co-operating structures", but not on the ground of the pronator-flexor group being the stronger. In the first place, there is nothing in the injury to excite these muscles to action; secondly, I cannot see how this group can be the stronger, unless we are to believe that a carpenter would drive a screw with greater force if the thread were reversed.

Again, if there have been an amputation below the elbow, the stump is drawn up, flexed. Is this because the biceps and brachialis anticus are stronger than the triceps? I do not think they are stronger; but further, the biceps is a powerful supinator, uninjured by the operation, yet the stump is always prone rather than supine.

It does so happen that there is one flexor muscle which, beyond all question, is stronger than its corresponding extensor: the flexor longus pollicis pedis; yet the great toe, at rest, or when a joint is inflamed, is always extended, never flexed. Moreover, to say that flexors are always stronger than extensors, is directly opposed to the teaching of Carpenter's *Physiology*, that "the extensors of the leg upon the thigh are much more powerful than the flexors, a character which is peculiar to man". We know the enormous strength of the extensor cruris in voluntary and involuntary action; but, upon what facts can it be asserted that the flexors are even stronger? I know of none.

I have felt it to be no light matter to differ from one of the great masters of surgery on a subject which he has made his own; but the opinions, which, to me, have at present the force of convictions, I am bound to express with no uncertain sound, or it would be vain to hope

\* Read before the Gloucestershire Branch.

for the free criticism I am now seeking. At any rate, I have endeavoured to look at the subject from every point of view. I had sought, in the first instance, for an explanation in some type of position of limbs in animals generally, towards which in rest they might revert. I had noticed that the position of all the limbs in a state of rest is a falling back towards the typical position in other mammalian animals; but one could only dismiss this as a curious circumstance, having no practical value. The question has, however, its practical side. Let us deal with it as affecting particular joints in disease.

First, as to the hip: One of the first symptoms of disease is a flattening of the nates, in other words, a wasting of the glutei, of which I would offer the following explanation: That the muscles are "told" of something wrong in the joint, and the glutei, so far from being excited to act, are led to remain quiet, wasting in consequence. The reason of this seems clear; for, if it be true that the commencement of hip-disease is almost invariably in the ligamentum teres, anything which causes this ligament to be stretched must be injurious. Now, the muscles which would do this, by drawing the limb outwards, *relax*; those which flex and draw it inwards, *contract*; and tension of the ligament is removed; "*harmony*" between the co-operating structures". It will be noticed, too, that another great ligament of the hip-joint is by this means made comparatively tense: this, the ilio-femoral, is relaxed when the thigh is flexed and everted, which is exactly what occurs when effusion into the joint stretches it.

The usual treatment of hip-disease is at once to put the limb straight, and so make the ligamentum teres comparatively tense; but the indication which I should deduce from the considerations set forth would be, to give the joint all the benefit of extension, both as regards steadiness, and relief of interarticular pressure, without changing it from the position of rest; and this may readily be done by extension from the knee, obliquely upwards and diagonally across the bed, a treatment which is actually recommended as a temporary measure when the limb cannot at once be put straight.

Mr. Hilton argues (pages 149-150), that the flexed position is not the easiest, because, in hip-disease, "when the femur is put straight and the flexed position is destroyed, the patient from that time is free from pain". Not "from that time", I should say, though it soon becomes less painful, provided means are adapted to fix the limb quite still, and further to relieve interarticular pressure; but surely it is not fair to contrast this with the limb left all to itself in its previous position. Further, it may be said that stretching of ligament, provided it be continuous, soon ceases to cause pain in any position: Nature has her remedy in absorption of the unyielding element, on a principle applied every day in the treatment of deformities by mechanical means.

The desire, on the part of surgeons, to treat fracture of the thigh in an oblique position, is a very old one; and if it be accepted, that what I describe as such is really the position of rest, the desire would be strengthened, as a means of preventing the tendency of the upper fragment to project and as less irksome to the patient.

Again, as regards the knee, though it is less easy to fulfil the conditions of extension while retaining the position of rest, it follows, if my views are right, that it ought to be done. And here let me revert to the old question of flexors and extensors. It seems to me that, given a flexion of the limb as a means of attaining the position of rest, it is not necessary to conclude that the flexors are the stronger because of the dislocation which follows. The flexors, in this position, draw in the same plane as the opposing surfaces of the bones; while the extensors, with whatever force they draw, so long as the flexors do not relax, can only pull the head of the tibia against the posterior surface of the condyles.

Lastly, as regards the ankle, if for any purpose we wish to maintain a state of complete rest of it, or of the parts around it, for the healing of an ulcer or other purpose, it follows that, looking to the "physiological harmony" of all the parts, the joint itself should be free from tension—should be in a position of rest; but the effect of fixing the foot at right angles to the leg, as is usually done, is to force the wide part of the astragalus between the malleoli and stretch the ligaments which hold them together. A more extended position of the foot with the knee bent is clearly indicated.

It will be observed that I draw my illustrations from the lower limb alone; the fact is, that the joints of the upper one are habitually treated in the position they naturally assume. And when we consider how numerous are the cases in which disease of the hip or knee goes on to destruction of the joint, and that these are the joints which are forcibly fixed in positions most widely differing from the position of rest, it would seem to be possible that in our persistent determination to fix limbs in what would be the best position, should ankylosis occur, we may be doing something towards making ankylosis the best result to be hoped for.

# CASE OF LARGE PROSTATIC CALCULUS. WITH NATURAL PERFORATION FOR THE URINE: REMOVED BY RECTO-URETHRAL LITHOTOMY, AFTER EXTRACTION OF A PENILE URETHRAL CALCULUS.\*

By RUSHTON PARKER, F.R.C.S.,

Assistant Surgeon to the Liverpool Royal Infirmary, etc.

THE patient was a man aged 54, a native of the Edinburgh district, who came under notice and submitted to operation in the first week of July 1877. Five years previously, he had suffered from difficulty of micturition and other urinary inconvenience, in consequence of which he had entered the Liverpool Royal Infirmary, where an operation was proposed and was on the point of being performed, but was frustrated on account of the fear and sudden departure of the patient. Since that time, he had had repetitions of the old trouble, but not to a severe extent until shortly before the date of the present observations, when he consulted his private medical attendant, Mr. T. W. Evans of Liverpool, who found a stone in his urethra, and sent him to me at the Stanley Hospital.

The penis was thickened, and very much hardened about its middle, and so tender that little examination could be endured. The urethra terminated anteriorly at the margin of the retracted prepuce, where it was wide enough to admit the point of a finger, being, in fact, now but a wide sinus. That part of the urethra which should traverse the glans penis had ceased to exist, owing to sloughing chances which he had had many years ago in India. There was, moreover, a fistulous perforation of the urethral floor about an inch behind the preputial orifice, of the width of a crow-quill.

Under ether, on July 6th, the penis was explored with forceps, and eventually a triangular stone was removed, less than three-fourths of an inch long, more than half an inch wide, and a quarter of an inch thick. The surfaces were irregular; one concave and the other convex. This stone lay in a space lined with granulations; a wide sinus, bounded by a portion of the urethra and corpus spongiosum.

On passing a sound towards the bladder, it stopped in the prostatic region, and struck a stone or stones. By the finger in the rectum, it was felt that the foreign material was close above the mucous membrane of the roof of the bowel. The prostate felt hard, slightly enlarged, and of the usual shape. The patient was then turned on his side, and the stone cut down upon with a small knife in the middle line of the roof of the rectum; the hole was enlarged forwards and backwards with a blunt-pointed bistoury, after which a calculus with several projecting lobes could be distinctly explored with the finger, but not easily dislodged. However, at last, with the aid of a scoop, the stone was removed.

The patient had a severe rigor shortly after the operation; but, in other respects, he has been very well. The wound was left to take its course. In two or three days, he had a stool. He has complete control over his feces, and urine when in small quantity; the latter escapes partly by the penis and in part *per anum*.

The treatment adopted was the administration of morphia subcutaneously for the first few days regularly, and afterwards when required. The diet was at first warm sago and water; afterwards bread and other farinaceous stuffs. Throughout, milk has been avoided.

The left testicle, which had years ago been swollen during his attack of syphilis, and which had dwindled down to small dimensions, became the seat of acute inflammation, which at its height was perceptibly relieved by the operation of a single leech. This complication was probably set up a fortnight after the original operation, on an exploration of the penis under ether, undertaken on account of persistent pain and tenderness in the organ, on the supposition that possibly some stone still lay unremoved. It was found, however, that the original operation had in this respect been complete. The case is still in progress, and the recto-prostatic aperture still remains; but I have thought that, in view of the extraordinary size, shape, and general circumstances of the stone concerned, its relation, at even this early period and in this imperfect form, would not be altogether inappropriate to the present occasion.

I have not been able to find any record of a prostatic stone, perforated in this manner and pervading the prostatic substances so completely as this has evidently done. The calculus has the shape of the prostate itself, with the addition of a promontory or spur at one end. Including the spur, the total length is  $1\frac{1}{2}$  inches; without it,  $1\frac{1}{4}$  inches. The greatest

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

width is a little over  $1\frac{1}{2}$  inches—strictly speaking,  $1\frac{2}{10}$  inches. The remaining diameter is  $1\frac{1}{4}$  inches. The canal runs parallel to the side which I take for the upper, at a distance below it of three-eighths of an inch, having a length of about half an inch, and opening forwards into a shallow groove on the surface in question, and extending along the promontory before referred to. Its horizontal diameter is an eighth of an inch, but the vertical less, so that a no larger catheter than a No. 2 of the English scale will pass.

The stone weighs  $1\frac{3}{8}$  ounces, is of a pale yellow colour outside, and paler within. One or two chipped surfaces show a laminated texture.

The only specimen I have seen which bears it any resemblance is one nearly as large, like it in structure, but unlike it in shape, in the possession of Mr. Bickersteth of Liverpool.

## PREVENTIVE MEDICINE IN ORDINARY MEDICAL PRACTICE :

BEING A SEQUEL TO DR. RANSOME'S ADDRESS ON  
STATE MEDICINE.\*

By WILLIAM OGLE, M.A., M.D., F.R.C.P.,  
Physician to the General Infirmary, Derby.

DR. RANSOME'S able address (BRITISH MEDICAL JOURNAL, August 18th, 1877) on State Medicine closes with some valuable suggestions to the legislature, and he indulges the hope that these suggestions may be adopted before many more years have elapsed. There is also a final paragraph asking for supplementary aid from "voluntary sanitary associations", similar to the one in Manchester.

It is principally to this concluding paragraph that I desire to direct your attention, and, indeed, to propose an amendment. I understand the word voluntary to mean "gratuitous". Against this I entertain a twofold objection. First, the profession is already overweighted with this kind of "voluntary" work; and, secondly, an agency is required much more comprehensive and thorough than any yet devised, even in Manchester, and one that is capable of doing work which it were both visionary and wrong to desire done by unpaid agents. I shall show presently how sanitary associations of this comprehensive, and, if you please, commercial, character might be organised, not only in large towns, but, as Dr. Ransome says, "in every locality". But, before doing so, and, indeed, by way of introduction, I must offer some remarks upon the hope expressed that the legislature will adopt a more enlightened sanitary policy, and in particular that it will give greater consideration to, or at least will not wholly ignore, the suggestions of medical men in framing new laws that relate to the prevention of disease. These two aspects of the question—the legislative and the voluntary, *i.e.*, the individual, are in fact inseparable.

At first sight, it may seem incredible that an enlightened Government should have framed laws for the preservation of the health of the people without a reference at every step to the medical profession. But the reason is not far to seek. Legislation cannot safely be very far in advance of public opinion. A little in advance it may and ought to be; but to be far ahead is not possible, nor, if possible, would it be workable, for the simple reason that obedience to law must be willing and intelligent if it is to be effective. Men cannot, even if they would, thoroughly carry out laws which they do not comprehend. This is my first remark. My second is that public opinion on medical questions is very much, if not better, yet not worse, than what the medical profession (in a past generation) has made it; and consequently that the faults in medical legislation, which Dr. Ransome has so fully and so justly exposed, must in some way or other, if not directly, then indirectly, which practically amounts to the same thing, be chargeable on the profession itself. If you will dispassionately look into this, you will perceive that the very same fault might be found with us for our defective mode of dealing with our patients that Dr. Ransome finds with the legislature for its mode of dealing with the profession. We ignore preventive medicine in ordinary medical practice; therefore, the public ignores us when it frames its preventive laws.

To establish this position, and to enlarge, as I desire to do, the scope of my observations, I beg you to notice that there is the same sequence observable in regard to the cure of disease. The relations between patient and doctor are very from being in accordance with the requirements of modern medicine, and consequently public opinion on curative measures is generally at fault. We allow the form of acknowledgment for our services to remain very much the same as when medi-

cine meant "physic"—little more, and certainly nothing less; and, as a natural consequence, the public puts its faith in physio and in nothing else, even when, as in homœopathy, there is nothing of physio but the name. Whilst medical charges continue to be based upon the quantity of medicine supplied, it will be to little purpose that Dr. Johnson (the same Dr. Johnson, be it observed, who gives castor-oil in cholera, and therefore not to be charged with scepticism as to the value of physio when physio is wanted) is bold enough to teach that typhoid fever is best treated solely by adjuvantia, such as careful diet and skilled nursing, and that many similar instances might be quoted on equally high authority. Payment "per bottle", or even "per visit", takes no account of enlightened methods of cure, and so to the general public they are unknown. In like manner, so long as the prevention of disease is ignored in the ordinary acknowledgment demanded for professional service, so long will the public most naturally conclude that prevention is not commonly regarded by us as any part of our duty; and the example of such noble men as Anstie, though emphasised by his death, so far as influence upon public opinion is concerned, is in a great measure lost.

The first step, therefore, towards the realisation of Dr. Ransome's most reasonable hopes of more enlightened sanitary legislation, should be for each of us who are engaged in the practice of our profession to consider our own ways.

To bring the question to a practical issue, I submit to the members of the British Medical Association the following proposals; viz.: (A) a thorough readjustment of our professional relations with the public on a preventive basis; and, second, arising out of this, (B) sanitary associations such as Dr. Ransome desires.

A.—The family doctor to be recognised as the "health-officer" of the family at all times, as well as the medical attendant in times of sickness. To make this possible, the acknowledgment for his services to be—*a.* A certain sum *per annum* for all ordinary work, including, of course, "preventive" work; *b.* Supplementary fees for extraordinary visits. Physio, whenever possible, to be supplied by druggists, or at least to be charged for separately.

1. The amount of the sum *per annum*, and of the exceptional supplementary fees to vary according to circumstances, and to be determined beforehand by private agreement between the doctor and his client.

2. The term "ordinary work" to include all attendances for which the request has been made at an early hour of the day—say by the time of the first postal delivery; also all visits made by members of the family to the doctor at his own house when he is "at home" for consultation. "Extraordinary visits" to be: night visits, but only such as are specially requested by the patient; Sunday visits, specially requested; and visits in obedience to summonses to come immediately, as to a confinement, or to a consultation, or, in short, at some particular time fixed by the patient.

In this simple way, the interests of the patient and the doctor become identical. The arrangement has been tried and proved satisfactory.

Proceeding on the same preventive principles, and calling in the aid of the principle of co-operation, sanitary associations may be formed "in every locality", but specially in large towns, "much more comprehensive and thorough than any yet devised". Thus—

B.—1. All *per annum* sums of, say, under ten guineas to be paid to a common fund.

II. Of these sums, the respective "family" doctors to receive only a part, a principal part, but only a proportion (say two-thirds or three-fourths). The remainder, which might readily amount to a large sum, to be held in trust for the general purposes of the Association, available for—

*a.* Exceptional payments by way of aid to the associated members, *e.g.*, supply of physio under exceptional circumstances (by provident dispensaries);\* organisation of hospitals and convalescent homes for the well-to-do, as suggested by Mr. Burdett, etc.

*b.* Expenses connected with the registration, as in Manchester, of disease; the purchase of expensive instruments, which, by reason of their cost, and that they are only occasionally wanted, are not within the reach of ninety-nine out of every one hundred medical men in the

\* Read in the Section of Public Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

\* Many years ago I studied carefully the working of all the then existing provident dispensaries in the kingdom. I came to the conclusion that the one at Coventry was the best; but even that I could not now recommend heartily without reservation. Provident dispensaries were a noble experiment forty years ago, but that is all that can be said in their favour. In the recent imitations of them—on the whole, inferior imitations—I see nothing to induce me to modify this opinion. I take, therefore, this opportunity of saying, that I believe provident dispensaries, unless they be as here suggested, part of a larger and more comprehensive scheme of efficient medical aid, will be found unworthy of confidence, and in regard to hospital abuses, will sooner or later be classed among the remedies that are worse than the disease.

country. For instance, how few provincial towns possess a (Ransome's) stethometer, or even a sphygmograph, etc.

c. An organisation of this kind would also secure the introduction without delay of the newest modes of treatment, e.g., the method of curing spinal curvature, which has been so ably demonstrated to this meeting by Dr. Sayre of New York, etc.

In short, these co-operative medical associations would proclaim to the public, in language not to be misunderstood, that the profession is resolved to make the prevention of disease, both infectious and other, not only a part but a principal part of its duty. And, further, that, for the cure of diseases not prevented, physic or no physic is not the main consideration, but simply how to cure them as thoroughly, as quickly, aye, and with as little cost to the community as is compatible with efficiency.

Improvement in sanitary legislation would follow. The public, becoming day by day practically acquainted with preventive medicine in their own homes, would learn the necessity for legislative measures, and then the Parliament would as naturally give to the profession its legitimate position, as now this is naturally withheld.

The words of Professor Stokes of Dublin addressed to the British Medical Association at Oxford (1868), on vacating the chair of the President, are so appropriate that I cannot conclude with words more apposite than the following.

"When medicine is in a position to command respect, be sure that its rewards will be proportionately increased and its status elevated. In the history of the human race, three objects of man's solicitude may be indicated: first, that of divinity; next, that of law or government; and, as man often seems to love gold more than life, the last is medicine. But, with the progress of society, a juster balance will obtain, conditionally that we work in the right direction, and make ourselves worthy to take a share in its government."—BRITISH MEDICAL JOURNAL, 1868, vol. ii, p. 125.

## THE THERAPEUTIC AND TOXIC ACTION OF SALICYLATE OF SODA.

By FREDERICK H. DALY, M.D., Dalston.

I HAVE used salicylate of soda a good deal, during the past twelve months, in cases of acute and subacute rheumatism; and the result of my experience of the drug is decidedly favourable. I have, like others, found it most useful in acute cases, when many joints are affected and where there is high temperature. Undoubtedly there is a greater tendency to relapse after treatment by this remedy than in those cases treated by alkalines and quinine; and it is remarkable for what a long period there is this liability to relapse, even after the pulse and temperature have been for days normal, if the salicylate be discontinued. The dose ought to be gradually diminished, and combined with a couple of grains of quinine three times a day. By this plan, the risk of relapse is greatly lessened. But all this is generally well known. My object in this note is to show how, in a single case, I had recently an opportunity of witnessing both the therapeutic and the toxic action of salicylate of soda.

On November 4th, I was sent for to see Mrs. B., aged 50, suffering from rheumatic fever in a severe form: both knees, one ankle, one shoulder, and both wrists were greatly swollen, and exquisitely painful. She was sweating profusely; the tongue was coated; and the temperature 103.2 deg. I ordered milk-diet and twenty grains of salicylate of soda every two hours. I again saw the patient in twenty-four hours. She had taken the twenty-grain dose regularly every two hours, and I found her quite free from pain, sweating very little, and the swelling nearly gone. The temperature was normal. She had slept very little, and was a little incoherent and inclined to call things and people by wrong names. She was ordered to take the salicylate every three hours. On the 6th, I found her quite delirious, refusing to take food or medicine, unless forced, and labouring under all kinds of absurd delusions. She appeared quite free from pain, and the temperature was still normal; but she had not slept at all and was wandering the whole night. She was ordered to stop the salicylate of soda, and to take an alkaline with quinine; also twenty-five grains of chloral-hydrate at bedtime. After my visit, the delirium became violent, but the chloral at bedtime gave six hours' sleep; and I found my patient next morning quite rational and much better, only complaining of pain in the right wrist. The urine was quite dark and contained a very little albumen. I resumed the salicylate of soda in ten-grain doses, with a grain of quinine, three times a day; and from this day there was no further trouble from the joints, but an attack of rheumatic conjunctivitis retarded the convalescence.

The above brief extract from my note-book needs no remark. My object is to draw attention to the toxic action of the salicylate, about which I have not seen much mentioned. I may remark that I have found small doses, repeated say every four hours, of little, if any, use in rheumatic fever. The remedy ought to be given every two hours for at least the first day.

## A CONTRIBUTION ON THE TREATMENT OF THE PROFESSIONAL DYSCINESIA.\*

By DR. LEONARDO BIANCHI,

Private Lecturer on Neuropathology and Medical Electricity in Naples.

IN the first number of *Il Morgagni* for 1873, I published a case of scribes' cramp, which, in a very short space of time, was cured with hypodermic injections of nitrate of strychnia. The young man whose case was the subject of that publication, at that time a student, is now a barrister, and has never since been troubled by the malady.

It appears, as far as I know, that since that time no other cases have been published in which the cure was obtained with hypodermic injections of strychnia, except one of Rossander, cited by Erb in Ziemssen's *Encyclopædia*. But I have had the opportunity of seeing many cases, the histories of which will be published in another work.

The views there expressed will perhaps be different from those expressed in my first publication. Therefore, putting aside for the present all pathological and physiological considerations, I will relate here some of these cases only, with the object of attracting the attention of this Association to the treatment of the disease.

CASE I.—In July 1873, I was consulted by Mr. D. L., a stout and strong man, for a disorder of his right arm. He informed me that he had been affected by it for six years, and had been prevented from writing by a painful feeling of tension and fatigue in every part of the arm and hand, with obstinate contraction of the supinators of the hand, turning it over; in the new position assumed by it, writing became impossible. Sensibility was undisturbed, and there was no difference, as regarded the muscular reaction with the faradic and galvanic currents, in the arms and forearms of the two sides. There were no painful points over the cervical spine. The faradic current applied for one month was quite useless; but he was very much improved by twelve injections of nitrate of strychnia; his writing became more regular, and he was less rapidly fatigued, as the contractions became less constant. He was then obliged to put off the treatment, on account of the necessity of writing, as he was occupied in a great deal of business which could not be left in other hands.

CASES II and III.—In 1874, I saw a man named Santilio, who consulted me on account of an irresistible and troublesome numbness of the right arm every time that he began little and delicate operations of the hand; viz., writing or sending telegraphic despatches. He was employed at the telegraph office, and the malady had manifested itself after two years of unusual and immoderate exercise of his profession. This is the second recorded case of telegraphists' cramp. The first was published in the *Lancet* in 1875, and it rather alarmed the English telegraphists. In my case, no spasm or contraction was observed in any muscle; but an irresistible torpor and sense of tension pervaded the entire arm when he attempted to write and to send telegraphic despatches, while he showed considerable strength in operations that required more muscular force and the exercise of both arms. There was no difference of reaction with the faradic current as regarded either the muscles or the nerves; but he sometimes felt pain on the cervical spine. He did not derive improvement either from muscular faradisation or from the continuous galvanic current, nor from injections of nitrate of strychnia, of which I made about thirty. I used two grains of the strychnia salt, after having ascertained that it was good by making experiments upon rabbits. The young man, who was very intelligent, assured me that his brother, employed at the Post Office, had suffered during about eight years from scribes' cramp, so much so that he was obliged to take an assistant for writing; and that, after the publication of my paper in *Il Morgagni*, he was completely cured by a number of hypodermic injections of nitrate of strychnia, and had resumed all the duties of his office.

CASE IV.—Mary D., a Sicilian, an elementary female teacher, had suffered during six years when she consulted me. She felt painful fatigue in every part of the right arm when she began to write, and had contractions of the interossei of the index and of the thumb, with also a slow contraction of the supinators, which, in the act of writing,

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

brought the hand into a state of supination, withdrawing it from the table. Her malady had developed itself after forced and prolonged writing in the schools. I saw her in 1875. A year before, she had been much relieved by fifteen injections of nitrate of strychnia, which were administered to her by Dr. Accetelli according to my recommendations. From that time, she was able to sew, having been quite unable to do so before, and to write during a longer period of time, which she was utterly incapable of doing previously. The treatment could not be continued for various reasons; nevertheless, the improvement has been constant, and she has persevered in sewing. There were no painful points on the cervical spine nor on the nerves of the arm; neither was there any difference in nutrition, nor in electro-muscular reaction, between the two arms, forearms, and hands.

CASE V.—I will relate a last observation, which, on account of the course of the malady and of the associated circumstances, is highly important and not less curious. Simone F. Paolo, aged 20, a native of Altamura, presented himself in my dispensary for nervous diseases at the end of June 1876, having been kindly sent to me by my friend Dr. Recchia. He was an intelligent, perhaps rather eccentric, youth. There was no previous history of nervous maladies. Being extremely fond of music, he had abandoned an honourable employment, which furnished him the means of an honest livelihood, and gave him the chance of happier prospects in the future, and left his paternal home for the purpose of indulging in his passion for music at Naples, where he was exposed to the most adverse fortune, with sufferings and privations of every sort. He ardently studied the flute, and soon became distinguished as a player on this instrument, studying about eight or ten hours a day. In that manner, two years passed away, when he began to feel a kind of torpor in the left arm, accompanied with pervading numbness. A few days afterwards, it returned, being now accompanied with irresistible hiccough that lasted day and night, and was not calmed by anything else but the electric current, which the lamented Professor Giannuzzi, his countryman, applied to his neck, using a large number of elements belonging to a telegraphic office; but neither the torpor nor the sense of numbness in the arm diminished; on the contrary, not long afterwards, he had a very limited cramp of the interosseal muscles of the ring-finger, so intense that, every time he played, he could not make the slightest use of that finger to open or shut the keys that he wished to; and he was soon obliged to desist from playing the flute, which was his only hope for the future. After having tried without success a great number of remedies, and also electricity with the interrupted current, he came to me, more discouraged and out of spirits than ever, and his incredulity seemed almost approaching to despair. His condition when I first saw him was as follows. He was robust and muscular, but pale, on account of the sufferings that he endured; the muscles of the arm, forearm, and left hand did not differ from those of the right side, either in density or in strength, or in the manner of responding to the constant and faradic currents. There was no difference as far as regarded the nervous reaction. He was capable of making any kind of movement, and of showing great muscular force; but he could not perform delicate and complicated operations, being hindered by the numbness, especially in the soft fleshy ends of the fingers. There was diminution of tactile sensibility in all the fingers, but without irregular movements. When he played the flute slowly, the left ring-finger rarely obeyed the will, but was impelled by lateral movements, in consequence of which it closed one of the keys higher or lower than he intended, so that the flute always produced a higher or lower tone with disagreeable discordance. If he made a greater effort of the will, the torpor and the cramp increased, so that, after a short time, he was obliged to desist from his unsuccessful attempt. I advised him to abandon all other treatment, and began to treat him with electricity. Having no hope of success from the faradic current, I employed from the beginning the continued current, applying it over the cervical and superior dorsal part of the spine, and a few times over the nerves. I used, at the same time, faradisation of the skin. The first symptom that disappeared was the anæsthesia; then the torpor began to diminish, so that after a fortnight the patient began to resume his musical studies, and after two months he was able to apply himself to them four or five hours a day without suffering much from torpor. However, the cramp of the ring-finger had not been greatly alleviated. After another month of electric treatment, the improvement totally ceased, and did not progress, notwithstanding my having persuaded him to desist from playing. It was then that I employed injections of nitrate of strychnia. I had prepared, as I have been accustomed to do in other cases, a solution of nitrate of strychnia, so that every *gramme* of the solution, representing the capacity of Liér's syringe, contained five *milligrammes* of the nitrate of strychnia. I began to use one *milligramme* and a half (.023 grain), and I increased the doses to

three *milligrammes* and a half (.054 grain) every other day. The injections were practised on the forearm; none of them were followed by inflammatory reaction, and after the tenth—that is to say, after twenty days of treatment—the patient told me that he was cured, and that his arm and his hand were firm. I also practised two other injections during a week after Simone had left my dispensary.

This young man passed his examination as a pupil with splendid success, and is remarkable for the rapidity with which he profits by the instructions he receives and his assiduity at study. I saw him last June, and no other symptom of the malady had reappeared.

I will not relate the other two cases of scribes' cramp treated by me, of which one completely recovered under this treatment, and the other obtained a great and durable improvement from the continuous galvanic current over the cervical spinal axis and the cervical sympathetic. With these results obtained by me from injections of strychnia, and electricity employed either alone or simultaneously, I think that I am authorised in considering the general prognosis of this disease as not so hopeless as it has hitherto been.

Among electrotherapists, Benedict is the only medical man with whom I am acquainted who considers the cure of this disease to be easy and frequent. Of about fifteen cases, he obtained in six or seven complete recovery, and in the others great improvement.\* Perhaps also Althaus has the same opinion as Benedict, although, in his esteemed book, he does not relate cases, and does not clearly manifest it. But all the other esteemed and conscientious electrotherapists,† among whom allow me to mention Rosenthal, Onimus and Legros, Erb, Crichton Browne, etc.; and a still greater number of pathologists, with the exception of Niemeyer, Jaccoud, Eulenburg, etc.,‡ do not show much confidence in the continuous constant current, with which they have more often obtained improvement than complete and durable recovery.

It is true that, on making an investigation of modern literature, many cases of recovery are found, as those of Hulke, Solly, Niemeyer, Meyer, etc. But we ought to consider that this malady occurs much oftener than is believed, and that recovery is often obtained after treatment of very long duration, as in the cases of Crisanto Zuradelli. For this reason, if another method of treatment help the action of electricity, offering a greater average of recoveries, as far as I have been able to judge from my cases, my communication will not be useless in the treatment of a disease considered so fatal to some arts.

With one patient only have I been unsuccessful, the telegraphist, in whose case a cure was not obtained either by the faradic current or by the continual constant current, or by cold baths, or by the hot baths of the island of Ischia.

I do not maintain that this treatment is always preferable; and, as neither the anatomical process upon which the malady depends, nor its seat, nor the mechanism, nor the clinical form is the same, so it is not improbable that there are cases in which electricity is available, and others in which hypodermic injections of strychnia are of more utility, and cure the patient in a shorter space of time.

It would be desirable to know in what manner strychnia exercises its medicinal influence in these disturbances of coordination; but, as neither experiment has aided pathological investigations in these cases, nor has morbid anatomy given any certain revelation as regards the anatomical changes, if there be any, that are determined in the muscles, nerves, and nerve-cells of the spinal cord, cerebral ganglia, etc., let me offer an hypothesis.

There are parietic forms of professional dyscinesie, of which cramp is but a casual phenomenon, arising from disturbed harmony of force amid the many muscular groups employed in the various and delicate actions of writing; and in such cases, if the disturbance be chiefly occasioned by the exhaustion of the groups of cells in the anterior grey substance of the superior part of the spinal cord, strychnia may be successful in raising the physiological power of the spinal marrow, and increasing its excitability. There are cases in which the continued stimulus produces a greater irritation in the above-mentioned centres, with pain in the corresponding points of the back-bone and on the nerves; and, if the malady be of long duration, with wasting of some of the muscles, especially of the interossei, in these cases I do not believe that strychnia can be of any utility. But, in many other cases, probably the mechanism of the cramp and of the dyscinesie depends on a primitive disturbance of coordination of the spinal marrow in its superior region, or of the cerebral ganglia. In these centres, or to speak more clearly, in the individual elements or groups of cells em-

\* Benedict, *Nervenpathologie und Electrotherapie*. Leipzig, 1874, p. 352.

† I must also except Duchenne and his school, who employed the faradic current, which is evidently less productive of results than the continuous constant current.

‡ *Lehrbuch der functionellen Nervenkrankheiten*. Berlin, 1871, pp. 684-695.

ployed, first with a long exercise of the will, and then almost spontaneously, it is necessary to admit, in order to understand the coordination, the passage and diffusion of the volitional and spontaneous stimulus exclusively in those elements that correspond with the muscles or groups of muscles upon which the execution of the harmonised and complicated movement is devolved. Now, the faculty of retention possessed by the cellular elements in the marrow and spinal cord may be diminished, and the stimulus may be diffused into other cells and other cellular groups; and these may then put into action other muscles or groups of muscles, by which the delicate action of writing, of telegraphing, of playing the piano or the flute, is disturbed.

I believe I can corroborate this hypothesis with an observation that I have made concerning a patient in my dispensary, in whom I found the ascending current incomparably more useful than the descending one, and there were not observed any signs of irritation either on the spine or over the nerves. By the use of the ascending current over the cervical spine for five or ten minutes, with twenty or twenty-five elements, a catelectrotic condition was produced, and in that manner the excitability of the spinal marrow was increased and the cramps were almost calmed. I am persuaded, by long observation which I have made upon this patient, that it was impossible to obtain the same effects with the descending current which produces the anelectrotic condition.

Although I have determined on not entering on the discussion of the physiological pathology of this disease, and analysing all the hypotheses, I believe that, as far as the treatment is concerned, the following assertions may be made without danger of contradiction.

1. The condition or the morbid process in the professional dyscinesia, and its seat, differ in different cases.
2. The difference in the disturbing process of the disease, in its seat, and in the mechanism by which the malady is determined, is perfectly in harmony with the difference of the clinical forms.
3. The prognosis may be considered less grave than most pathologists believe.
4. The treatment, electric or internal, in order that it may obtain a greater average of recoveries, must be conformable to the clinical character of the disease, which differs in various cases, and which must indicate when the ascending or the descending current may have a better effect on the spinal cord and on the nerves, when simultaneous faradisation of the muscles and of the skin (disturbance of tactile sense) may be applied with success, when galvanisation of the brain or of the sympathetic nerves in the neck is useful, and when the hypodermic injections of strychnia, exclusively or associated with an established method of electrification, may be of more utility.

## ANTEVERSION OF THE LIVER SIMULATING ENLARGEMENT.\*

By T. D. GRIFFITHS, M.D., Swansea.

It appears that anteversion, or rotation forwards of the liver, on its own transverse axis, is not very uncommon. In this abnormal position, the anterior border of the liver falls below the ribs, the upper surface is turned forwards, and the hepatic dullness in the nipple-line is increased. This increase of dullness is in proportion to the degree of anteversion; in extreme cases, it becomes equal to the diameter of the liver in the antero-posterior direction. It is, therefore, important to recognise this displacement, as it simulates enlargement of the organ, and may, in this way, embarrass the physician, and lead him astray in his diagnosis. To illustrate my position, I shall briefly refer to three cases.

CASE I.—Mrs. B., aged 27, a tradesman's wife, of dark complexion, average stature, moderately well fleshed, has been married a little over three years, has had two children; the younger child was born a year ago. The patient consulted me in December last about "a lump in her stomach", which she had noticed since her previous confinement, and which she attributed to her nurse's neglect, who had not, as she supposed, bandaged her properly.

On examination, there was no visible prominence over the hepatic region when the patient lay on her back. The abdominal wall was wrinkled, and marked with "silvery streaks"; it was also soft and yielding on palpation. The lump in the stomach for which the patient sought advice was evidently the liver. It was easily felt by the hand, and appeared much larger than natural; the anterior edge extended down into the iliac fossa, and was easily grasped between the fingers. The hepatic dullness in the right nipple-line was seven inches, extending from the upper border of the sixth rib into the iliac fossa; the sur-

face was even and smooth, and without any indentation. It was very movable—it could be pushed under the ribs—but was not tender on pressure. There was no history of tight lacing. The left kidney was easily felt, and movable. The uterus was retroflexed. The spleen was normal in size. The heart and lungs were healthy. Digestion was normal. In short, the patient's general health was very good, and she complained of nothing, but wanted to know the nature of "the lump in her stomach", which caused her no discomfort or inconvenience. There was no doubt as to what this lump was; it could be felt, and even manipulated, through the abdominal wall. It was the liver, which was, apparently, very much larger than natural; but there was nothing besides this apparent enlargement indicative of disease in the organ itself. And there was nothing whatever to show that the liver had been pushed down from its natural position. The spine was normal. The thorax was well formed. There was no effusion in either of the pleural cavities. The heart was healthy, and there was no effusion in the pericardium, and, as far as I could ascertain, there was no tumour between the liver and diaphragm; but the abdominal wall was lax and limp, almost like washleather. The liver could be pushed upwards and made to assume its normal size and position. It was, therefore, evident that the enlargement was only apparent, due to rotation forwards, or anteversion.

With the view to improve the atonic and atrophied condition of the abdominal wall, and of the recti muscles in particular, Stohrer's interrupted current was applied, from five to ten minutes, every other day, for three months. It was only after repeated applications that the lower half of the recti muscles began to respond to the current. At the end of three months, the silvery streaks and the loose wrinkled condition of the skin had almost entirely disappeared, and the muscular condition of the wall had greatly improved.\*

I have notes of several other cases of this kind in women who have borne children, but I will only allude to one of them, the first I ever noticed, some twelve years ago, and over which I blundered slightly.

CASE II.—Mrs. S., aged 60, a mother of a large family, of spare habit of body, below the average in height, of gouty constitution. When I was called in to see her, she was suffering from acute dyspepsia, and she had been failing in general health for some time previously. On examination, the abdomen was found very much in the same state as in the last case. The liver was apparently very large, and, in addition, it was slightly tender on pressure. There was nothing to show that it had been displaced by any intrathoracic disease, or by deformity of the chest-wall, curvature of the spine, or tight lacing. There was no history of gall-stones or of intemperance, and the enlargement could not be accounted for by simple congestion. Considering the apparent size of the liver, together with the symptoms and previous history, I was inclined to believe that the patient had some malignant disease of the liver. However, after a time, the tenderness of the liver passed away, the dyspeptic symptoms disappeared, and the patient recovered her usual health; but the apparent size of the liver remained the same, and I was able to satisfy myself afterwards that it was simply due to anteversion.

CASE III.—A. B., † aged 54, of fine physique, tall and stout in proportion, and somewhat corpulent. When he first came under my observation, in February 1875, his liver was found smaller than natural, the hepatic dullness in the nipple-line was from 2 to 2½ inches. Without going into the whole history, suffice it to say, that the case was diagnosed as cirrhosis of the liver. When the patient was again examined, in July 1876, the liver was found very much in the same state as to size. Towards the latter end of November last, one of the leading London physicians, an eminent authority on diseases of the liver, saw the patient with me in consultation. There was now a marked change for the worse in the patient's general condition; he was lethargic and drowsy, slightly jaundiced, emaciated, and confined to bed. There was no elevation of temperature; the liver was slightly tender on pressure; the hepatic dullness now extended from two fingers' breadth below the nipple to the crest of the ilium, and partly into the iliac fossa, eight inches vertically in the nipple-line. The edge of the liver was easily felt, as the full and prominent belly had become retracted and the abdominal wall flaccid and emaciated. With the exception of being very slightly emphysematous, the lungs were healthy. And, although there were well marked mitral regurgitant disease and hypertrophy of the heart, there was no apparent abnormal dilatation of the right side, nor indeed any cardiac trouble.

\* To faradise both recti muscles, the rheophores should be applied to the seventh intercostal space, a little outside the nipple line on each side; and to act on one side only, one pole of the battery should be applied in the seventh intercostal space, and the other immediately above Poupart's ligament, midway between the superior iliac spine and symphysis pubis.

† This case was fully reported at a meeting of the Pathological Society of London.

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

Having excluded the ordinary possible causes of spurious enlargement of the liver, and having considered the previous history together with the then present physical signs and symptoms, the physician already alluded to was satisfied that we had mainly to deal with a *large* cirrhotic liver. Some months previously, according to my own observations, the organ was small and contracted. To account for this apparent increase in size was somewhat puzzling. The theories of congestion, cancer, etc., were considered, and dismissed as an unsatisfactory explanation. This apparent enlargement remained until the patient died, some months afterwards. At the *post mortem* examination, the liver was found lying on its under surface in the lumbar region, the anterior edge of the right lobe being down in the iliac fossa. The liver measured 12 inches transversely, 8 inches in the antero-posterior direction, and 2½ inches in the thickest part, and weighed 56 ounces—a small liver for the size of the body from which it had been taken.

*Remarks.*—The predisposing causes of anteversion of the liver appear to be distension of the abdominal cavity, followed by the opposite condition, and at the same time attended with atrophy of the recti muscles. With the distension of the abdominal cavity, the wall in front is expanded and the round ligament of the liver is stretched and lengthened. When the distension is afterwards removed, the abdominal muscles in front having previously become atrophied and lost their tonicity, the support of the anterior border of the liver is taken away.

### SOME STATISTICS OF SMALL-POX.

By HENRY TOMKINS, M.D.,

House-Physician to the Royal Infirmary, Manchester; late Resident Medical Officer at the Munsall Fever Hospital.

IN the BRITISH MEDICAL JOURNAL for October 20th there appeared an article devoted to the consideration of a paper written by Mr. T. B. Sprague in the *Journal of the Institute of Actuaries*, in which some small-pox statistics compiled by Dr. Keller of Austria are strangely at variance with those published in this country, and notably those of the Metropolitan Asylum Hospitals. As a small contribution to the same subject, the following notes may be of some value in arriving at a more satisfactory conclusion than that of the above named writer as to the efficacy of vaccination in affording protection from small-pox, when performed in a proper manner and at proper intervals of time.

The cases from which the following tables have been formed were those received into the Munsall Fever Hospital, Manchester, from the 1st of January to the 31st of December, 1876, and for the accuracy of which I hold myself responsible. During that year, variola was present in an epidemic form in Manchester and its suburbs, being at its height during the spring and early summer months; and, although these cases represent but a small proportion of the total number recorded in this district, being less than one-half the number recorded by Dr. Keller and scarcely one-fifteenth of those treated in the Metropolitan Asylum Hospitals during the epidemic of 1871-72, still, as they were received from all parts of the city, they may fairly be taken as representing the average mortality of the disease in this district during the epidemic of last year.

Arranged below is the total number of cases, with the average mortality of the vaccinated and unvaccinated, compared side by side with Dr. Keller's and with those of the Metropolitan Asylums.

TABLE I.—*Death-Rate in Cases of Small Pox.*

	Cases.	Deaths.	Death-Rate per 100.		
			Munsall.	Dr. Keller.	Met. Asyl.
Vaccinated with one or more distinct cicatrices . . . . .	745	71	9.53	16.4	10.2
Unvaccinated cases . . . . .	78	45	57.7	24.8	44.8
Said to be vaccinated, but no cicatrix visible . . . . .	37	13	35.13		
Not known whether vaccinated . .	61	29	47.54		
Total . . . . .	921	159	17.1	18.7	18.7

In all these, the death-rates of the total number are about the same, and they agree in being higher among the unvaccinated than amongst the vaccinated. Dr. Keller, however, makes the remarkable statement that, *except during infancy*, the mortality is much higher amongst the vaccinated cases, and brings forward figures to prove this assertion.

In the article of the BRITISH MEDICAL JOURNAL before alluded to, the mortality of the cases under five years of age from Dr. Keller's reports is compared with that of the Metropolitan Asylum Hospitals. I have analysed the cases at Munsall in the same manner, and find them still more at variance with Dr. Keller's. Thus:

TABLE II.—*Cases of Variola at Five Years of Age and under.*

	Cases.	Deaths.	Munsall.	Rate per 100.	
				Dr. Keller.	Met. Asyl.
Vaccinated with one or more distinct scars . . . . .	21	1	4.8	38.6	19.5
Unvaccinated cases . . . . .	23	19	82.6	33.3	61.2
Said to be vaccinated, but no scar visible . . . . .	7	3	42.8		

In all statistics, there is a liability to draw false deductions; and, in quoting the above, it should be stated that, owing to a prevalent idea abroad in this part of the country, that parents are liable to punishment for the omission of vaccination when this is discovered by the occurrence of variola, it is often difficult to get them to acknowledge non-vaccination, and therefore it is not unlikely that some of those cases said to be vaccinated, but no scar, were really unvaccinated; and the same with those set down as not known. But, after allowing for this, the plain fact still stands out most prominently, that immense protection is undoubtedly afforded by successful vaccination; and, in conclusion, I would earnestly commend the following to the careful attention of those zealous but misguided individuals who are constantly clamouring against vaccination and its compulsory performance. Firstly, in the nine hundred and twenty-one cases at the Munsall Hospital treated during the year 1876, in those where there was any evidence of vaccination at all, the death-rate was but 9½ per cent. Secondly, amongst children under five years of age, where there was a distinct cicatrix, there was but *one* death in the twenty-one cases under treatment, and this solitary one was a poor puny child, whose death was occasioned quite as much by diarrhoea as by small-pox; whilst amongst the twenty-three unvaccinated cases, only four recovered. Not a single death occurred among adults where successful revaccination had been performed within four years; and, lastly, out of all the numerous workpeople coming into the hospital during the year as porters, labourers, servants, nurses, etc., not *one* contracted small-pox, every individual being compelled to be vaccinated before commencing work there.

One other point is worthy of consideration. It is this: in a population where compulsory vaccination is in active operation, it may fairly be assumed that the children who escape vaccination are in an extreme minority; and yet out of this minority a larger number of cases were received than from amongst the exceedingly large majority of vaccinated children. What, then, would have been the number had the unvaccinated been in the majority, and what the number of deaths at the rate of 82.6 per 100?

### THERAPEUTIC MEMORANDA.

#### THE TREATMENT OF OBSTINATE SICKNESS BY KOUMISS.

I WISH to record briefly the result of my experience in the treatment of obstinate sickness by koumiss; for I believe, with Dr. Jagielski, that we possess here a simple but a satisfactory remedy, and one likely to be of use when the ordinary remedies fail.

Miss S., aged 31, far advanced in phthisis, and already much exhausted by incessant cough, profuse sputa, sweats, and diarrhoea, was suddenly attacked by hæmoptysis, accompanied by obstinate and distressing sickness. The patient was *in extremis*. After exhausting the ordinary remedies, I administered, cautiously at first, No. 2 koumiss with the best results. The sickness immediately ceased; the hæmoptysis merged into tinged sputa and gradually disappeared; the pulse became stronger; the skin warm and moist; the diarrhoea ceased. The patient, who had previously loathed all food, gratefully took the koumiss, at first alone, then mixed with milk. A return of hæmoptysis in the fourth week, with secondary bronchitis, took her off.

Miss T., aged 50, was attacked by hæmatemesis (due probably to gastric ulcer) and persistent vomiting. Iced drinks, gallic acid, etc., failed to give much relief; for, when food was taken, the sickness and hæmatemesis returned. We were reduced to the treatment by enemata of beef-tea and brandy, which was continued for five days, notwithstanding which the patient became much weaker. No. 2 koumiss was then given, as in the last case, with good results.

In a case of severe vomiting caused by mental shock, but remotely connected with concussion of the spine, the result of a carriage accident, koumiss No. 1, made from the extract, was successful after hydrocyanic acid, bismuth, creasote, etc., had failed.

In several other cases, I have given koumiss, and always (except

when malignant disease was present) with good result. In stricture of the colon (the diagnosis being subsequently established by *post mortem* examination), it relieved the pain and attendant sickness, and prolonged life. In the vomiting of pregnancy and in obstinate constipation I have seen it do good.

RICHARD LOWTHER, M.D., Cartmel.

#### TREATMENT OF TETANUS BY CHLORAL.

In the JOURNAL for January 5th, are given cases of tetanus treated by chloral-hydrate; I wish to add to the cases there given two in my own practice.

A boy, aged 11, had tetanus caused by a lacerated wound of the hand. He was treated by full doses of chloral-hydrate, resulting in complete recovery. This case occurred about nine years ago.

The other patient was a man aged 40, whose finger was lacerated by machinery. Forty grains of chloral produced almost immediate relief. The drug was administered in reduced doses for a fortnight, resulting also in a complete recovery. The spasms in this case were torturing in the extreme; and the man's life was despaired of. The marvellous influence of the drug was most marked.

GEO. MILES, M.R.C.S., L.S.A., Plympton, Devon.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### GUY'S HOSPITAL.

DR. PAVY'S WARDS.

*Malignant Disease of the Liver.*—A woman aged 53, rather emaciated and of a dark swarthy complexion, was admitted to the clinical wards, complaining of weakness and a dragging pain on the left side of the body, which she attributed to the effects of "a strain" received four weeks previously. On examination, the thoracic viscera appeared normal. The abdomen was distended, and the liver could be plainly felt through the thin abdominal walls; it was very large, and its margins could be plainly felt; the edge was well defined, hard and nodular; the notch was felt opposite to the umbilicus; and the left lobe appeared enlarged out of all proportion to the size of the right lobe; in parts it was very tender on palpation and presented an elastic feel. There was no jaundice. The urine was normal and free from bile-pigment. The patient was much troubled with dyspeptic symptoms. No other indication of malignant disease in the abdomen or elsewhere could be obtained; but there was a suspicious little tumour in the neck, rounded, movable, and not adherent to the skin. This might prove to be cancerous, but at present there was no indication of this. The woman said it had been coming about a fortnight.

A diagnosis was made of malignant disease of the liver. The history and physical condition did not correspond with those of cirrhosis; the surface of the liver was distinctly nodular; the whole organ was much enlarged, especially the left lobe. A cirrhotic liver may be nodulated, but this is not usual till the stage of contraction is advanced. In this case also, the somewhat irregular enlargement of the liver, the tenderness of certain parts of it, the age of the patient, and the dark swarthy complexion, were mentioned as points indicative of malignant disease.

The presence of lardaceous disease was rendered improbable by the absence of chronic suppuration and syphilis. Further, there were no other signs of lardaceous disease, no disturbance of the bowels, and no albuminuria. She was ordered iodide of potassium, in five-grain doses, three times a day.

*Enteric Fever.*—A young woman was convalescing from a rather mild attack of enteric fever, having almost completed the third week of the disease. The temperature had never been higher than 102 deg. Fahr.; the bowels throughout the illness had been rather loose, but not tender. The spleen was not enlarged. Dr. Pavy remarked that it was favourable to see the patient lying upon her side, as indicating that she had plenty of power. The rash had almost died away, no fresh spots having appeared for some days; but the disease could not be considered as gone till the spots entirely disappeared. The prognosis appeared good; but it was impossible to tell what might happen. A relapse might come on, hæmorrhage or perforation might occur; a guarded prognosis was, therefore, necessary. In this respect, a more

cautious opinion must be expressed in a case of enteric fever than is necessary in typhus. In enteric fever, it is difficult to ascertain with certainty the condition of the bowels; there may be much sloughing of Peyer's patches, or the congestion may subside without the occurrence of ulceration.

*Chronic Bright's Disease.*—A woman was admitted, complaining of severe pain in her head and almost total loss of sight in her right eye. She was thirty years of age, and had been failing in strength four years. Two years ago, she had moderate and transient arasarca for some months. A month ago, she was attacked with convulsions, in which consciousness was completely lost. On recovering from this attack, she found that she was almost blind with the right eye. Ophthalmoscopic examination revealed a large hæmorrhage in the fundus of the eye. The urine was albuminous; of specific gravity 1015, pale in colour. No casts could be found, but occasionally a few blood-corpuscles could be seen. The heart and vessels appeared normal. Dr. Pavy considered this as probably a case of contracted granular kidneys, the vascular system not as yet having become diseased. It appeared to be a case in which the kidney-disease was primary, and not dependent upon a general vascular change, such as without doubt often precedes the local renal disease. It was then pointed out how important it is to test the urine in cases of continuous headache, especially if the arterial tension be high.

*Salicylic Acid in Acute Rheumatism.*—Dr. Pavy has obtained very favourable results in using salicylic acid in the treatment of acute rheumatism. He usually prescribes twenty-grain doses of the acid, dissolved with liquor ammoniæ acetatis or carbonate of soda, to be given at first every two hours; and believes that, while reducing the temperature and relieving the pain, it also prevents endocarditis and other complications, if commenced early enough. The more acute the case, the more reliable is the action of the drug; but in all cases it is essential to continue its administration, in diminished doses, for at least a fortnight after the subsidence of the fever; if this be neglected, relapses are very apt to follow.

*Diabetes Mellitus.*—Two cases of diabetes were under observation. In the clinical investigation of diabetes, Dr. Pavy observes the condition of the urine and of the blood while the patient is taking a mixed diet. The blood is drawn by cupping; the amount of sugar is determined by the following method. The blood is first mixed with sulphate of soda, and heated to separate the albuminoids and colouring matters; the liquid is then separated, and the coagulum well washed to remove all the sugar. The liquid is next boiled with an excess of the copper solution, and the reduced suboxide is afterwards collected and dissolved by the agency of an acid. In this solution a cylinder of platinum foil is immersed, for the purpose of receiving the copper removed by means of galvanic action. Weighing the platinum foil before and after the operation, gives the weight of the deposited copper; and from this may be calculated the amount of sugar which has effected the reduction of the cupric oxide (see *Proceedings of the Royal Society*, No. 182, 1877).

Dr. Pavy usually treats his diabetic patients with codeia or opium, and a restricted diet. The pre-ent patient was ordered powdered opium and extract of nux vomica, of each half a grain, in a pill three times a day.

*Ulceration of the Bile-Ducts and Suppuration of the Liver.*—A woman was attacked, six weeks before her death, with severe paroxysmal abdominal pains, together with shivering and feverish symptoms, which were attributed by her medical attendant to the presence of gall-stones. When admitted to the hospital, she was manifestly ill and moderately jaundiced; the abdomen was distended; the liver enlarged, but not tender; and no distinct tumour could be felt. The spleen was normal. The temperature was generally low; but, towards the end of the case, it varied from 101 deg. Fahr. to 103 deg. Fahr. There was no vomiting. The diagnosis appeared to lie between some form of blood-poisoning and disease of the liver, either malignant disease or cirrhosis.

At the necropsy, the liver was found to be large, the gall-bladder was empty and contracted, the common duct was ulcerated and contracted, all the ducts in the liver were dilated, the capsule of the liver was much thickened, and diffused suppuration was found throughout the substance of the organ.

It appeared probable that gall-stones had caused obstruction of the common duct, leading to ulceration, dilatation of the hepatic ducts, and finally suppuration of the liver.

*Cerebral Hæmorrhage in a Young Man.*—A young man aged 23 had died from extensive hæmorrhage into the right ventricle, which burst through into the fourth ventricle; no coarse change was seen in the cerebral vessels, the heart, or kidneys. A dark-brown scar in the corpus striatum of the opposite side indicated a former slight hæmorrhage, corresponding to a slight hemiplegic attack a year before.

Extensive cerebral hæmorrhage in a young subject, presenting no coarse visceral disease, being exceedingly rare, it appeared probable that a small aneurism might have ruptured; the vessels were, therefore, macerated, and reserved for microscopic examination.

## REVIEWS AND NOTICES.

LECTURES ON CLINICAL MEDICINE, delivered in the Royal and Western Infirmarys of Glasgow. By Dr. MCCALL ANDERSON, Professor of Clinical Medicine in the University of Glasgow, 1877. Pp. 268. London: Macmillan and Co. 1877.

THIS volume consists of seventeen clinical lectures delivered by Dr. MCCALL ANDERSON in Glasgow, and forms a valuable addition to our medical literature.

As in other clinical treatises, we do not look merely for a record of new discoveries, but rather for good clinical descriptions and the faithful records of sound clinical work, whereby we may increase our familiarity with the natural history of disease and receive hints as to the best methods of clinical study and clinical teaching. In these particulars, we are well pleased with the volume before us.

Clinical teaching is year by year becoming more systematic; and, as years go on, it must adapt itself to a wider range of knowledge, and afford instruction in the more refined and elaborate methods of physical examination. In the works published from time to time by our clinical teachers, it is interesting to observe the methods by which each endeavours to impart clinical instruction. Dr. McCall Anderson teaches his students at the bedside, by demonstrating selected cases to classes of moderate size, and also in the class-room by means of clinical lectures. In this work, he is aided by medical tutors, senior students acting under his direction, who give individual instruction to the younger students in the methods of examining patients, etc. By these means, the class have ample opportunities of gaining practical knowledge.

In his introductory chapter, the importance of observing symptoms is dwelt upon, and the methods of observing are briefly described; while their usefulness is impressed by the records of cases illustrating their successful employment in the art of diagnosis.

The second chapter is devoted to cases illustrative of Pain as a symptom of disease, and introduces the student to the study of subjective symptoms, at the same time urging, in the absence of signs of coarse disease, the necessity for seeking the diathetic indications of the case, as the presence of syphilis, gout, or rheumatism. In this, as in succeeding chapters, the interest is excited and maintained by the narration of cases of considerable interest in illustration of the teaching given, and this renders the work throughout very suggestive to the student and to the practitioner.

The subject of Aortic Aneurism occupies three lectures, and several cases are recorded of successful treatment by galvano-puncture. The cases recommended for this treatment are those in which the tumour bulges forward from the surface of the chest; the method pursued is as follows. The skin having been frozen by ether-spray, needles carefully insulated to within half an inch of their points are thrust into the aneurism, being passed obliquely into the sac; these needles are then connected with the positive pole of a large-cell Stohrer's battery; a zinc plate connected with the negative pole being applied to the chest-wall on the opposite side, and about three inches beyond the edge of the swelling, a sponge wrung out of warm salt water intervening between the zinc plate and the skin. Six or eight cells are used in most cases. In the first case narrated, a prominent tumour, of the size of a hen's egg, pointed near the root of the neck; it was distinctly expansile, and very soft; a vibrating "purring tremor" was felt over it, and it presented other signs of an aneurism of the arch of the aorta. As the tumour increased in size, galvano-puncture was decided upon; and this was carried out four times in all. After the second operation, the tumour was somewhat firmer; on one occasion, two needles were employed, one connected with either pole of the battery. On withdrawing them, no blood escaped from the opening made by the positive needle; but when the negative needle was removed a jet of blood spurted out; this was, however, soon stopped. As a result of this treatment, the tumour underwent considerable solidification, and the patient was able to resume active work for some weeks, though she eventually returned to the hospital and died. The *post mortem* examination showed that the sac was filled with old and recent clots, and a very distinct stratified coagulum, paler and firmer than the rest, indicated the line of one of the needles. An illustration represents the pathological appearances.

In another chapter, we find a clear and graphic sketch of the Cirrhotic form of Bright's Disease; comments are made upon the case of a

man who presented many of the natural characteristics and complications of the disease, including retinitis albuminurica and cerebral hæmorrhage. Several drawings are given in illustration of the pathology of the case. We observe here, as in other chapters, that the author, while describing the disease, seeks to impress the facts upon his hearers by frequent reference to the case under notice, and thus sustains their interest in the subject.

Space forbids us to go further than briefly to notice an interesting case of Ephidrosis Cruenta, which occurred in a young lady. From certain rounded patches on the face, arms, and chest, somewhat resembling erythema, there occurred at times attacks of hæmorrhage; each attack was preceded by a burning pain. At times, the exudation was like water, but more often actual blood flowed as from a cut surface. These patches usually healed quickly, but some suppurated. Menstruation was very irregular. After a twelvemonth's duration, the disease passed away.

This work presents many other points of interest upon which we have been unable to touch, and is likely to prove of much value to all who study it.

THE MEDICAL DIGEST: being a Means of Ready Reference to the Principal Contributions to Medical Science during the last Thirty Years. By RICHARD NEALE, M.D., etc. London: The New Sydenham Society. 1877.

CONSIDERING the vast extent and complexity of medical literature, the deficiency of collated indices to many large portions of it is very remarkable. Each half-yearly volume of our weekly journals contains its own index—a long and cumbrous document; and thus each year accumulates, in London alone, at least a dozen indices, which must all be separately looked through by any one desirous to ascertain what has been written on any given subject. The labour involved, if it be wished to go over a series of years, is simply appalling. Hence the back volumes of our journals rapidly lose in value, for their treasures can be got at only by the zealous student, or under circumstances of urgent necessity. Several of our Societies, the Royal Medical and Chirurgical and the Pathological, for instance, have published indices to their whole series of *Transactions*; but nothing of the kind, until the present volume, has been attempted for any part of the weekly press. The work just issued by the New Sydenham Society is, however, not a mere index, nor, on the other hand, is it a complete index. It professes to be a Digest, by which term it is intended, we suppose, to express that special arrangements have been made, by bringing into juxtaposition references to the same subject, to save the time and trouble of the reader. Dr. NEALE's plan is very simple, and at the same time admirably concise and clear. His references are classified under headings, which are printed in capitals, and numbered and sub-numbered; and thus, instead of being obliged to look down a long column, the reader may find the subject of which he is in search in many cases without reading an unnecessary line. The Index alone, as we are told in the preface, contains 9,000 references; and these include, in the body of the work, nearly ten times as many entries.

The work was not, it appears, written for the Society; but, having been prepared by Dr. NEALE for his own use, was offered in its complete state to the Council. We have no hesitation in expressing the opinion that it is one of the most valuable which the Society has yet issued, and shall be much surprised if, when it becomes known, it do not acquire a high reputation. In saying this, we by no means ignore its defects. It is, in the first place, an index to only a small part of even English medical journals—chiefly, indeed, to the *Lancet*, *Medical Times*, and *Medico-Chirurgical Review*—for the last thirty years; nor for these is it exhaustive. Dr. Neale has evidently selected according to his own tastes and appreciation of value; and it is difficult, in many instances, to guess his reasons for notice or omission to notice. Taking the work, however, for what it is, and not for what it is not, we may pronounce it a remarkable effort of industrious and successful collation. The real test of the work is to use it, and this we have had occasion to do frequently since it came into our hands. We can testify that it gains greatly on acquaintance. To the not very numerous persons who possess a set of back volumes of either the *Medical Times* or *Lancet*, it will be especially valuable, and will convert what was almost useless from its cumbrousness into a library of medical knowledge of easy reference. Nor is the book, although compiled confessedly for those in general practice, likely to be less valued by authors, editors, librarians, and all who have access to public collections of books. Its pages will save time and temper immensely to those to whom time and temper are most valuable. That its incompleteness, and perhaps now and then its errors, may occasionally annoy is not to be denied. It is written rather for those who can be grateful for posi-

tive help than for those who insist on absent excellences. No one who has looked up the references which its pages afford must suppose that he has found all that has been recently written on the subject of his search. He will, however, have certainly found much, and that very easily; and, if he desire completeness, at any rate part of his labour will have been saved. As it is, with all its very conspicuous imperfections, we accept Dr. Neale's Digest as a boon to the profession, and as likely to prove a great help to medical research.

**BENGAL MEDICAL REGULATIONS FOR BRITISH TROOPS.** Non-Official Supplement to Part I, Bengal Medical Regulations. Calcutta: 1877.

The appearance of these regulations, in neat and portable volumes, recently issued by authority from the Government Printing Office at Calcutta, must be very welcome, not only to the officers of the British Medical Department, but to all those whose duties bring them into official relations with the medical establishment of Her Majesty's British Forces in Bengal; and those who are similarly connected with the Army Medical Department at home and in the colonies may well desire that the fragmentary pamphlets of rules issued from time to time from the office in Whitehall Yard, were available in so concise, well-arranged, and complete a form.

The Bengal Medical Regulations, which had been the sole guide for medical officers and others up to 1857, were abrogated by the code published in 1873; but the compilation of a new code, in supersession of that bulky volume, became a necessity, owing to the recent changes in the condition of the Army Medical Department, and its altered relations to the Government of India, the Military Departments, and the Local Medical Service. The task of compilation was undertaken by Surgeon-Major Ogilvie, Secretary to the Principal Medical Officer; and the volumes under notice are the outcome of much labour on the part of that officer. Dr. Ogilvie had had some years' experience of the administration of the Army Medical Department in the office of the Director-General in London; and, while retaining all that was good in the obsolete local regulations, he has engrafted into the new code much that is intended to assimilate the working of the department in India to the customs obtaining in other parts of the world.

The contents of the official volume are divided into thirteen sections, and these again into subsections and numbered paragraphs, with marginal headings, for easy reference. The first section deals with the administration of the department, and the relations of the administrative officers to the several authorities; while the mode and conditions of their appointment, and all details connected with their duties, are clearly laid down. Section ii naturally treats of the executive, and epitomises the multifarious duties of surgeons-major and surgeons under almost every circumstance; while Sections iii and iv contain the rules for the subordinate departments, including the several classes of apothecaries, hospital assistants, and purveyors. The subject of hospitals is dealt with in Section v, including those in cantonments, and those to be formed during war; and under the head of establishments, are laid down the rules for hospital sergeants, writers, nurses, and servants. The mode and sources of supply for the maintenance and conduct of the medical establishments are explained in a separate section, No. vii; and in that following are all the rules connected with the increasingly important subject of hill sanatoria. The regulations for sick leave, and the invaliding of officers and soldiers are laid down in detail in Section ix; and in Section x are issued such clear instruction on the subject of medical attendance to be afforded, as must prevent unpleasantness in connection with that hitherto fruitful source of misunderstanding. The duties while on the march, on shipboard, and when moving by rail, form the subject of a section by themselves, and are very complete.

As might be expected, the rules relative to sanitation form an important section; and if space allowed, it would be of interest to point out how much is now officially done to contribute to the health and comfort of the troops. We can but mention that, alike for troops in garrison or the field, on road or railway, if the rules laid down are carried out little remains to be done. Under sanitation, too, are treated the means for prevention of venereal disease; those for preventing the outbreak of cholera and limiting its spread, as well as that of small-pox, and the subjects of filtration of water and disinfection of bedding, clothing, and buildings, complete the section.

Last, but not least, is the section dealing with returns to be sent in to the several departments; and while noticing how complete are the rules laid down, we cannot but lament that the "red tape" element is still so important that the instructions alone, without any specimen blank forms, occupy 84 out of the 250 pages which comprise the volume; exactly one-third of its entire size, and three times as much as is devoted to sanitation. Appended to the regulations is a "non-

official supplement" of great value. It contains the most recent warrants for the army medical officers and the subordinate departments, as well as the latest rules for pay, pensions, and allowances under all circumstances; clear and ample references being given in the margin to all rules and orders on the subjects. Scales of equipment and supplies are given, and specimens of all blank forms are added. Still more important are the instructions relative to cholera, and the mode of conducting inquiries respecting it, forming as they do an epitome of all recent sanitary investigations. Useful information is added on the modes of cleaning and charging filters; on the native names of drugs and other articles of use; on postal rules and recruit examination; and finally and appropriately on the duties connected with the homeward voyage.

It is impossible in a brief notice to do justice to the new code. Dr. Ogilvie has brought a faculty for organisation and arrangement to bear upon an important subject; and he has constructed, from a somewhat chaotic mass of materials, scattered far and wide, a code of regulations which, for clearness, conciseness, and completeness, leaves little to be desired. It is not too much to say that, provided with the new Bengal Medical Regulations and the non-official supplement, the medical officers of Her Majesty's service will have a *Vade Mecum* which, from the time of their arrival, throughout their Indian service, and to their return to England, will give them full instructions that, if carried out with care and ordinary skill, must conduce to the welfare of the soldier and the good of the service.

**ILLUSTRATIONS OF CLINICAL SURGERY:** Plates, Photographs, Woodcuts, Diagrams, etc., illustrating Surgical Disease, Symptoms, and Accidents. By JONATHAN HUTCHINSON, F.R.C.S. London: J. and A. Churchill.

WE have already expressed a very high opinion of the value of this important contribution to medical literature, and each succeeding fasciculus confirms and increases our estimate. It presents a quite unrivalled series of pictures, most of which are of great fidelity and pictorial beauty, of interesting forms of disease observed with accuracy throughout a career of large and varied experience, and discussed with clinical sagacity and sincere observance of the true methods of research. Amongst the subjects treated are inherited syphilis, mercurial vaccinosyphilis, deforming rheumatism, cheiro-pompholyx and xanthelasma palpebrarum, injuries of the head and bones, etc. Few men, if any, in the profession have at their disposal so great wealth of clinical material as Mr. HUTCHINSON has collected with unwearying patience for a long series of years in more than one vast field of observation. The work promises to be one which no surgeon will willingly omit from his collection, and which will certainly do honour to British surgery. The artist, Mr. Burgess, is well known as a draughtsman of great fidelity and skill, and the publishers have produced the plates in a style which does them credit.

**NEW ORTHOPRAXY:** the Mechanical Treatment of Deformities, Debilities, and Deficiencies of the Human Frame. By HENRY HEATHER BIGG, Associate Institute C.E. Third Edition, revised, enlarged, with 319 Illustrations. London: J. and A. Churchill. 1877.

MR. HEATHER BIGG's well-known and valuable practical treatise has achieved just popularity, with steadily increasing success. In this third edition, it has grown to notable dimensions, which it has legitimately acquired by the gradual accretion of an increasing experience from a large field of practical observation. Mechanical therapeutics have come to play a very important part in what are here comprehensively described as deformities, debilities, and deficiencies of the human frame; and no doubt benefit has resulted from the very careful study given to the improvement of mechanical devices and apparatus, and to the invention of special appliances for unusual cases by men of large experience and intelligence, such as Mr. Bigg. Increased attention has been given in this volume to the preventive treatment of spinal curvature, and the section on gymnastics of the spine is carefully treated and will be read with profit. We are inclined to think that Dr. Sayre's recently published book on the use of the plaster-jacket in the treatment of spinal curvature will supersede a vast deal of instrument-making for that purpose, and will make every general practitioner his own instrument-maker to a large extent, for which purpose he requires only a suitable flannel jacket bandage and a basin of plaster of Paris. But, while the field of orthopædics may thus be narrowed in one direction, it is constantly increasing in others; and the interest and extent of subjects treated in this work suffice to indicate how much of progress has been made, and how great services may yet be rendered by skilled mechanics who possess the requisite anatomical knowledge.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 19TH, 1878.

A LOST MEDICAL SCHOOL.

OUR pages this week include a continuation of the correspondence commenced three weeks ago, in which a series of important statements have been laid before the profession concerning the once famous Medical School of the University of Oxford. This correspondence has discussed the state of the Medical School of Oxford, and has disclosed a present state of things and a historical series of facts which certainly deserve prompt and serious consideration, and seem to call for deliberate and very vigorous action. When first the statements contained in the letter of "A Member of Convocation" were brought under our notice, they appeared to us of so unexpected and remarkable a character, that, but for the excellent means of information at the command of "A Member of Convocation", and the obvious attention which he had given to the subject, as well as the great importance of the question in its general relation to the progress of medicine and the privileges of the medical profession, we should have hesitated to allow it to appear. An investigation of the subject, however, afforded us grounds for believing that substantially, as regards the facts themselves, and irrespectively of any personal relation to them of the eminent men whose names he cites, the statements which he brings forward have so large a mass of evidence in support of them as to be at least deserving of the thorough sifting which they are likely to have when published in the columns of this JOURNAL. "A Member of Convocation" very closely connects the decadence of the Medical School at Oxford with the name and the acts of a medical man than whom no one has more amply testified, by his public statements and by his public functions, to a deep interest in the progress of medical science, the maintenance of medical interests, and the development of medical education. Dr. Acland is known to all the profession, not only as Regius Professor at Oxford, but also as the President of the General Medical Council of Great Britain, and as having taken a large and active part in the promotion of the costly Museum of Physical Science at Oxford; he is also known as having devoted a large amount of time and consideration to questions of public health and organisation of preventive medicine. As a past President of the British Medical Association, which he received with generous hospitality at Oxford, and to whose prosperity and public influence he largely contributed during his period of active association with it, and since then and to this moment, we can testify to the active and large interest which he takes in the promotion of legislative or other action which tends to the highest interests of medicine and the medical profession. Dr. Acland cannot, however, have lived a life of busy public occupation, and held important public offices, without being aware that his public acts are open to free debate, and if necessary to arraignment. This is especially the case in respect to the method in which those functions have been carried out, when a *prima facie* case is made out supporting the view that, however good or however wise the intentions may appear to have been by which he has regulated the performance of those functions, the result has not been satisfactory.

Such investigation as we have made of the present and past history of the Medical School at Oxford appears to show that there is ground for saying, irrespectively of any individuals, that the decadence of the Oxford School of Medicine is not only a serious loss to the University and to the profession, but that it has been accompanied, and has been largely due, to a diversion of funds intended for the purpose of medical education; and that the present state of things calls urgently for a sweeping measure of reform, such as can only be carried out upon application to the recently appointed University Commissioners for a large measure of reorganisation. Great medical names are connected with the early history of the Medical School of Oxford—the names of Harvey, Radcliffe, Willis, and its many benefactors. Linacre and Lee left large funds, which have been slowly but systematically diverted from the study of medicine, until at last the Medical School, as "A Member of Convocation" states, has been squeezed out of existence, and until the Medical Faculty of the University has been, within the last few years, completely abolished. Our correspondent, in his first letter, wrote:

"At a recent date, the Medical Faculty of the University of Oxford preserved a nominal existence; and in the *University Gazette* we read—Medical Faculty: Regius Professor, H. W. Acland (no lectures); Clinical Professor, H. W. Acland (no lectures). This, however, probably exposed too plainly the peculiar manner in which Dr. Acland understands his duty to the profession and in which he administers his historic office. The Faculty has, therefore, been removed from even nominal existence, and this professorship appears now only under the head of Physical Science and Mathematics, to which latter department it is probably considered more properly to belong, as having only an abstract existence. The Professorship of Physiology and Anatomy is scheduled under the same heading, the contempt of its incumbent for medicine being thus officially proclaimed."

Two Oxford Graduates of Medicine, writing on January 12th, whilst paying an eloquent tribute to the personal merits of Dr. Acland and Dr. Rolleston, concluded their letter by affirming that medical education at Oxford is now a scandal and disgrace to the University by its absence.

In order to remind ourselves by what course of proceedings the present state of things has been brought about, we have to remember that Dr. Acland holds at the present moment, as "A Member of Convocation" this week points out, the combined offices of Regius Professor of Medicine, Aldrichian Professor of Medicine, and Lord Lichfield's Clinical Professor, as well as those of Chief Examiner of the Medical Faculty, and Radcliffe Librarian; the sum total of the activities of the three professorships combined in one person are alleged to be represented by the notices in the *University Gazette* which have been quoted. Although notices have at regular intervals appeared in the papers which led many to suppose what they were probably not intended to lead any one to suppose, that the Regius Professor and the Clinical Professor was in the habit of affording regular instruction in medicine and in clinical medicine to Oxford medical students, it appears from the statements of "A Member of Convocation" that such is not the fact.

As to Dr. Rolleston, whose high attainments as a comparative anatomist and physiologist are so well known as to render any tribute from us superfluous, he will probably not contend that he has been in the habit of teaching human anatomy and physiology in the manner customary in other medical schools or intended for ordinary medical use; and, whatever may be the excellent reasons which have prevailed in his mind in divorcing the professorship which he holds from the regular course of medical education, he will probably be one of the first to admit that he has not included in his instruction a course of physiology and histology such as is required by the examining bodies, with the approval of the General Medical Council, as the base of a sound medical education.

But we have had to point out that the whole story is not told, if attention be confined to the clinical professorships of medicine and to the professor-

ship of physiology. There exists at Oxford a Trust Fund of considerable annual value, which, in addition to the endowments of which we have spoken, would make up a large part of the annual funds requisite for the establishment of a staff and a system of teaching as would make the Medical School of Oxford a reality; and these funds have been often more flagrantly diverted from the service of medicine than have been the funds designed to endow the chairs already spoken of. On this subject, our readers will find the Blue Book containing the report and evidence of the University Commission, published in 1852, and that of the University Commission (Revenue), published in 1874, invaluable as throwing light on the determined misappropriation to other purposes of funds originally applicable to the furtherance of medical study in the University of Oxford.

A Trust Fund was left by Dr. Matthew Lee to Christ Church, Oxford, for the sole and express purpose of providing for the study of human anatomy. The Blue-Book of 1874 shows, if we rightly read it, that this fund is now actually no less in value than £3,400 annually. It also shows in what way the governing body of Christ Church are spending the money. Of the whole £3,400, only £294 is paid to a teacher of anatomy; and this not to a teacher of human anatomy, but to a gentleman learned in details of zoology. *Not a farthing of Dr. Lee's bequest is now used in the interests of medicine.* Christ Church is actually allowed to employ the remaining £3,100 of Lee's fund in making the following payments; viz.: a Reader in Chemistry, £294; a Reader in Physics, £294; a College Lecturer in History (can malversation go further?), £294; a Mathematical Lecturer, £50; expenses of the Chemical Laboratory, £500; and (perhaps the most preposterous perversion of the fund of all) to boys from Westminster School, as "scholarships" awarded for classical attainment, £1,200.

It is really an affecting thing to read by the side of the above figures the will of the excellent Dr. Matthew Lee, dated August 27th, 1755. It is to be found on page 282 of the Blue-Book of 1852. Dr. Lee gives the most precise directions as to the duties and payment of his anatomical lecturer, for whose support alone his bequest was intended, although he did not expect the property left by him to realise more than one hundred pounds a year. The lecturer was to be a layman. He is to be paid his salary "half-yearly for ever". He "shall take, teach, and instruct no pupils in any art or science whatever except anatomy, physick, or botany; and shall go through two regular and complete courses of anatomy every year, in each of which he shall dissect at least one adult human body". Poor Dr. Lee further directed the Dean of Christ Church to withhold from the reader his salary if he had failed on any occasion to dissect and expound a human body in the half-year for which the salary was due. These provisions were made and solemnly accepted only one hundred and twenty years since. For fifty years there has been no more attempt to carry them out than would be expected were solemn compacts the work of lunatics.

From the Blue-Book of 1852, it is obvious that the systematic neglect of medicine, though now, it is alleged, developed to an extreme, had reached a high pitch under the late Regius Professor, Dr. Kidd. This gentleman stated with great *naïveté*, in his evidence (Blue-Book of 1852, p. 256) before the Commissioners: "On the subject of medicine I have never been called on to lecture, partly because it has been an universal custom, for the last sixty years at least, for the medical students of Oxford to resort to the London or other schools for the purpose of attending lectures on the Theory and Practice of Medicine as soon as they had taken their degree of Bachelor in Arts at Oxford; and partly because the very few who wished for information on the subject of medicine during their undergraduateship preferred an attendance on the lectures delivered by Lord Lichfield's Clinical Professor at the Radcliffe Infirmary." It is, of course, not irrelevant here to

notice that Dr. Kidd's successor as Regius Professor—namely, Dr. Acland—has been appointed also to the Clinical Professorship; and that that office has, it is alleged, become, like the Regius Professorship, a sinecure.

We had hoped to have had, perhaps, the benefit of Dr. Acland's remarks upon the correspondence thus far; but it would be unjust to complain of his reticence. He may object to answer correspondents who, while singling him out by name, have not given their own; though that is a discomfort to which the incumbents of public offices soon become accustomed; and it is obvious that not every one who feels it his duty to point out a public grievance feels called upon to do more than to give to the editor of the journal to which he writes the requisite proofs of his personal *bona fides* and right to be heard on the subject. Dr. Acland may, perhaps, on the other hand, decline to come forward as a champion of a system of which he recognises the abuses, and with which he has possibly only a powerless and unwilling association. We prefer to think the latter the more probable hypothesis; and, at any rate, while we have thought it our duty to do all that can forward free discussion and prompt reform of the present state of the Medical School of Oxford, we anticipate that we shall find Dr. Acland in what, from the whole tenour of his public utterances and acts, we believe to be his place of predilection—in the van of a reforming movement. For such a movement we hope the recent publications in these pages have now given the signal. The moment is unquestionably opportune. The shame to the University of Oxford of such a state of things as has been described appears great and crying. The highest educational interests of the profession are involved, and the usefulness of the University has been seriously damaged. The graduates of the University, both in medicine and, we would fain hope, in other faculties, will no doubt feel it now to be their duty to form an organisation for the purpose of pressing upon the University Commissioners the necessity of putting an end to such a state of things as has been disclosed, and restoring to Oxford, in whatever form or however modified, its "lost School of Medicine". Nor can the profession at large be expected to stand by unmoved, now that we have put fairly before them the history of the past, the promise of the future, and the outline and schedule of their wasted heritage.

#### PHYSICIANS AND FEES.

THE correspondence on the subject of the relations of physicians, practitioners, and patients, and of medical fees, is being carried on in our papers by writers, many of whom occupy eminent positions in the profession, and who are, in their respective spheres, in the best position to judge of the difficulties of which they speak, and of the advisability of the suggestions which they make; and we could wish that they should have added to their letters their own signatures, which would have given great additional weight to their writings. However, the mere fact that so many eminent men should take part in the discussion, indicates the large hold which it has at the present moment on professional attention. The letter signed by Mr. Crombie, and relating to a circumstance at Aberdeen to which a former correspondent had called attention, is of particular value, as illustrating the very mixed nature of the duties and classes between which a sharp line is sometimes drawn, and the local character of distinctions thus made. It would seem that in Aberdeen, as our correspondent of the 29th ultimo states, a gentleman holding the position of Professor in the University, and the appointment of Surgeon at the British Court, has for some years acted as surgeon to a small club of eighty members, almost wholly belonging to the operative classes, at a stipend of £10 *per annum*, made up by small uniform contributions from the members. Mr. Crombie, the secretary of the club in question, explains the circumstance; and observes that in Aberdeen, as in other provincial towns in Scotland, there is no distinction made between the con-

sultant and the general practitioner. He adds, that he could not see what injury the club in question has done to anyone by availing itself of the services of its distinguished medical attendant, and that the yearly stipend is surely too trifling to excite envy or ill-feeling. We may perhaps agree with him that the club has done no one any injury, and that there is, in the stipend of £10 *per annum*, nothing to excite envy or ill-feeling; nevertheless, the situation is one calculated to excite considerable interest, as throwing light upon the relative position of consultants and general practitioners, and the extent to which the duties, emoluments, and relations of the various classes are sometimes mixed; and its main interest, at the present moment, is an apposite illustration of the difficulties to be solved if any attempt is to be made to maintain distinctions between these classes, and to arrive at any sort of understanding of what is the relative position of the members of the profession distinguished by such titles, and what principle is to guide the tariffs of fees demanded. It has to be considered in the light of this example, whether the limit is to be solely at the upper end of the scale, so that the consultant shall never charge more than a guinea if the patient consult him at home, but may be, without objection, brought down at the lower end of the scale to a sixpenny or a shilling fee, which, we presume, would be the maximum payment for individual cases calculated upon an annual stipend of £10 for eighty members. In order to arrive at any conclusion as to these limits, cases in the different parts of the Kingdom, in the great cities of Scotland and Ireland, as well as of England, should be brought before the profession, so that it may be determined how far any understanding arrived at is to be local or general.

#### NAVAL MEDICAL ADMINISTRATION.

THE question of the premeditated changes in the government of naval medical establishments was, it is alleged, raised through an article which appeared in a weekly naval paper about a month ago, instigated through pique and animosity against the head of a naval hospital. If that be so, we regret that better means were not taken for making public such causes of complaint. There are, however, good grounds for doubting whether the Admiralty contemplates the changes spoken of, for there has been no complaint raised by them against the present system, and until a charge is brought against the medical officers, there is no occasion for them to stand upon their defence. *Qui s'excuse s'accuse*. Nor is there, we think, any reason why they should make the changes which have been proposed. It has been said that they would act upon the ground of discipline. Now, as to this, the reply is clear that no executive could act without consulting the medical authorities, and the experience of a gentleman of many years' standing and of high repute in naval medical affairs is that the *suaviter in modo* is the strongest law; and that, moreover, as no power to punish was ever vested in captains superintending hospitals, beyond confining a patient to bed, with the sanction of the medical officer, there is no reason here to return to the former state.

Another motive assigned is that there should be a check upon the too powerful medical element, or some one who would look upon proposed alterations and suggestions for improvement from a disinterested point of view. But is not the "common sense" of one man equal to that of another, whether he be a captain or a doctor? And so also should be power and sense to govern a large establishment for the cure and relief of suffering, from which the elimination of military rule has done more to conduce to the comfort of the inmates than the feeling that military discipline follows them to their bedside, and that, even in their walks in the grounds, they must also be always on the alert to stand straight and turn their eyes right or left. Nor, indeed, are sick persons the most likely to be guilty of a want of proper respect.

Whatever the good expected from this proposed change on public grounds by the agitators in this matter, in justice to those who now hold the office and to those who have preceded them, a fair trial should be allowed; and if found wanting, they should be treated according to

their deserts. Nothing better could be desired, than to see a fair report of what has been done in naval hospitals during the time they have been under the superintendence of medical heads. We question whether, in one in particular, of which we have taken special notice, under other rule, so few changes in the personal staff of the hospital, whether of the attendants on the sick or labourers who work in the grounds and offices, would have taken place, or more have been done to improve their comfort without deteriorating from their efficiency; while, at the same time, there has been complete harmony between the medical chief and the other officers, and the establishment has been maintained in a state of complete efficiency. Similar results, we are assured, would be generally found to have been attained in the other institutions which would be affected by the changes proposed; and this is entirely in accordance with the experience of those great county asylums, as at Wakefield, where the medical superintendent has been invested with general governing power.

#### FOUND DROWNED.

WHAT is the meaning of the verdict "Found drowned", often returned by coroners' waterside juries in inquests on bodies taken from the river Thames? Would it not be more correct to record a verdict of "*Found dead*"? But the inconvenient question might then arise between the coroner and the magistrates who pay the expenses of these inquiries—Of what use is an inquest, when the waterman who picked up the body could arrive at the conclusion just as readily and upon as safe grounds as the twelve discreet persons summoned as jurors by the coroner? The verdict is surely based on a mistake. The body is not found "drowned", but simply "in the water"; and so the verdict ought to run in a large proportion of these cases, in which no *post mortem* examination is either ordered or made. We are induced to make these remarks from the report of an inquest held on December 22nd by Mr. Humphreys, at a tavern in Poplar, on the body of a gentleman aged 35, found floating in the river Thames. George Harrison Abbott, a lighterman, stated that on Thursday morning he found the body of the deceased floating in the Thames off Blackwall Pier. George Sander, Inspector of the Thames Police, stated that the deceased was dressed in dark tweed trousers and vest, but *no coat*. All the under-linen was of a superior quality. The button-hole of the vest showed that the deceased had worn an Albert chain. In his pockets were one shilling and twopence, and a pocket-knife. The body, which bore *severe marks of violence*, had been in the water about ten days. Dr. Bramfield, police-surgeon, who had examined the body, said the injuries had been inflicted *before death* by some sharp instrument. Mr. Thomas Gray, surgeon, said he had examined the body, and found a *severe cut over the left eye, caused by a sharp instrument*. The right eye was black and much swollen; *the bridge of the nose was broken; the cheek-bone had been flattened into the face*; and the left eye was severely contused; but no other bones were broken. All these injuries had been inflicted *before death*. The cause of death was *drowning*. A photograph of the body had been taken. A verdict of "Found drowned" was recorded.

We are at a loss to reconcile the medical opinion and the verdict of the jury with the state of the body. The "severe marks of violence" on the body inflicted by a sharp instrument, and, as it is alleged, all bearing the appearance of having been inflicted before death, are medical facts not consistent with death by drowning, unless we assume that there had been a violent struggle with assassins on board of some vessel or on the banks of the river immediately before submersion.

The marks of violence found on the body are wholly unlike those which are seen on the bodies of drowned persons as the result of accidental collisions with anchors, chains, or other objects in a tidal river, after death. Besides, we presume that the two medical gentlemen had good reasons for stating that all the injuries had been inflicted *before death*; and, so far as they are described, they appear to be adequate to account for death. The injuries to the face were such as

were likely to be followed by insensibility, and to prevent a person receiving them from making any effort to save himself if immediately thrown into water. There was nothing about them to indicate suicide; and the only conclusion to be drawn is, that this was really a case of homicide, probably murder, preceded by robbery.

It is loosely stated that the cause of death was drowning; but there is no evidence of this. So far as the report allows us to judge, the body was inspected externally, but no internal examination was made. At any rate, there is no account of the appearances on which the medical witnesses relied to show that the deceased had really died from drowning, or that he had gone into the water living. After a dead body has been floating in a river for ten days, it would be somewhat difficult to express a positive opinion on this point.

In our view, all the facts proved at this inquest render it highly probable that this was an act of murder screened by the verdict of the coroner's jury "Found drowned"; one of many which, we believe, occur yearly in the metropolis under similar circumstances. No *post mortem* examination of bodies taken from the river is usually made; and whether the persons have died in the water from drowning, or out of the water from murderous violence, the bodies being afterwards thrown into the river for concealment of the crime, remains a matter of conjecture; the inquiry of the coroner being commonly satisfied by the evidence that the body was found in the river, and therefore "Found drowned".

This case will, no doubt, appear in the registration returns of deaths as one of drowning. It will form an erroneous unit of the large number of cases of alleged drowning which occur annually in London, and will, of course, mislead the statistician who is dealing with the causes of death. To give our readers some idea of the number of these so-called drowning cases which occur yearly in and around London, we may state that according to the returns for ten years from 1858 to 1867 there were 3,367 deaths registered in London from this cause; 2,965 by accident (as returned), and 402 by suicide. At the present date, with the increase of population, they probably do not average fewer than from 350 to 400 *per annum*. As to murder by drowning, it will be practically ignored until the present perfunctory method of conducting these inquests is abolished. In a large number of these cases, the unsatisfactory verdict of "Found dead" would be more appropriate than "Found drowned". Under a new system of conducting such inquiries, we may hope to have mortuaries like the Morgue in Paris, to which all drowned bodies may be taken, and there undergo a proper medico-legal examination, without permitting that indecent exposure whereby the dead bodies in the Morgue are made a public exhibition.

DR. J. S. TAYLOR has been appointed, not without protest, medical officer of health for Liverpool, in the room of the late Dr. Trench.

DR. PATRICK HERON WATSON of Edinburgh accompanies Lord Rosslyn as one of his suite as the deputation to Madrid to represent the English Court at the wedding of the King of Spain.

DR. GUY, F.R.S., is nominated one of the Commissioners to hold the inquiry relative to convict prisons, promised by the Secretary of State last session.

WE regret to see announced the death of Dr. James Blundell, the famous accoucheur, which had on more than one occasion been erroneously reported. Dr. Blundell died at his house in Piccadilly on January 15th, aged 87. We must reserve further notice until next week.

THE paper by Dr. Bastian which we published in the last number was the concluding part of a communication now in course of publication in the fourteenth volume of the *Transactions* of the Zoological Section of the Linnean Society; and it was read by him to the Society summer.

THE Earl of Derby is, we are glad to hear, favourably convalescing from a sharp attack of dysentery, which has compelled his absence from the recent Cabinet Councils.

#### UNIVERSITY OF LONDON.

At a meeting of Convocation on Tuesday last, the new Charter for admitting women to all degrees in the University of London was approved by a large majority. Sir William Jenner, Dr. Quain, Mr. Lister, and others, spoke expressing their disapproval; Dr. Pye-Smith, Mr. Hensman, and Mr. Bompas speaking in support of it. It is, however, understood that the question of the best method of acting upon the Charter will be left to the consideration of the medical members of the Senate.

#### FRIENDS OF ADULTERATION.

THE Justices of Pembrokeshire have decided, in answer to a renewed application from the Local Government Board on the subject, that it is unnecessary at present to appoint a public analyst.

#### MILK-STANDARDS.

THE present standard of purity, or rather of impurity, accepted in the London police courts in respect to milk, is eminently unsatisfactory, and facilitates large and systematic frauds on the public. The Society of Public Analysts, after long deliberations, adopted a limit in the case of milk which allowed the milk of an ordinary healthy cow to be diluted with five per cent. of water, and yet pass without condemnation. This in itself was a doubtful proceeding; but the *employés* at Somerset House have apparently capped it by taking as a standard the poorest possible milk that ever man extracted from a cow under any circumstances; and they have seemingly finally decided that, as far as they are concerned, average milk with twenty per cent. of added water should be passed as genuine, lest by chance the proprietor of a diseased or underfed cow should accidentally suffer, say once in twenty years. Such a conclusion is, the *Analyst* holds, as lamentable as it is ridiculous, and against all preconceived notions of public morality. In that opinion we entirely concur; and we may add that its practical effect is to place the public entirely at the mercy of the milk-dealers, many of whom largely profit by it to dilute and skim the milk to such an extent as to rob it of twenty-five per cent. of its nutritive properties, and then retail it at the highest price and under cover of the most imposing misstatements.

#### THE TREATMENT OF CONFIRMED DRUNKARDS.

THE Mayor of Boston appointed lately a Committee of three, consisting of Rev. Dr. A. A. Miner, Dr. George C. Shattuck, and Dr. John E. Tyler, to examine and report on the treatment of drunkenness in the city institutions, and to suggest some measures for the reform of this class. The report of the Commission, as stated in the *American Quarterly Journal of Inebriety*, appears to be worthy of attention. They condemn the method of dealing with drunkards by which men and women arrested and charged with intoxication are fined in some small amount, generally ten dollars, or sent to a workhouse or penitentiary for some short period, commonly thirty days. If the fine be paid, the burden falls upon the family or friends of the drunkard, who are innocent of all fault, and are sufficiently punished by the mere fact of his drunkenness. If he be sent to prison, the term of his confinement is long enough for him to get sober, but not long enough for him to acquire habits of sobriety. The consequence is, they say, that a restoration to liberty is followed by a new outbreak and another commitment. The police statistics of London and New York establish this fact, in their opinion, beyond all doubt. The worst defect, however, of this method of punishment is its failure to make any distinction between drunkards and criminals. These conclusions lead to the recommendation which the commissioners make for a new mode of proceeding in the treatment of inebriates. They suggest that the city of Boston should convert the institution at Deer Island into a sort of reformatory, where all kinds of agricultural and mechanical labour can

be carried on. Thither drunkards should be sent for terms long enough to enable their constitutions to recover thoroughly from the effects of alcohol and to give them an opportunity to acquire habits of industry. In some cases, a year would be sufficient for this purpose; in others, three years might be required. There would be enough of punishment involved in the reformatory process to make it thoroughly salutary. So long as the present system of fines and temporary imprisonment serves to manufacture drunkards instead of reforming them, this topic of the relation and duties of the community towards inebriates will continue to be of the highest interest in all countries; and we on this side of the Atlantic, who have already been greatly influenced in this matter by American precedents, shall attentively watch the result of any fresh experiments at Boston.

#### SALT IN BEER.

PROFESSOR BERNAYS, Public Analyst for Camberwell, makes some statements in his last report which are very important in relation to a recent prosecution. In the past quarter, he has examined eleven specimens of beer, ale, and porter. As to alcohol, except in a spruce-beer which contained 14.3 per cent., the variation was only between 8 and 10.5 per cent. The same lack of hops is exhibited as of old; at least, a little goes a long way. But the most curious feature is in the increase of salt. He has mentioned the almost absence of salt in days gone by. Now, however, we have arrived at a quantity, in one case, so large that he obtained a magisterial decision and a penalty, reduced, at the request of Mr. Marsden, from £10 to £5, together with costs. He gives examples, stating the grains per gallon: No. 57, not estimable; 58, 5.60; 59, 11.20; 68, 13.30; 67, 30.10; —, 32.90; 63, 34.30; 61, 44.10; 60, 47.69; 69, 58.10; 70, 82.60. Here, then, we have, from a merely nominal presence, as much as eighty-two three-fifths grains of salt in a gallon: a quantity sufficient to induce thirst and to encourage drunkenness.

#### HOSPITAL SUNDAY IN LIVERPOOL.

SUNDAY last was the eighth anniversary of Hospital Sunday in Liverpool, and, so far as is at present known, the results promise very satisfactorily. The total sum realised by the Sunday collections and "Saturday boxes" has for some years averaged £10,000, at an annual expense of three per cent. The late Mayor (Sir A. B. Walker) remarked that this sum would, if capitalised, represent a sum of £200,000. It may not be unprofitable to point out the chief causes to which Liverpool owes its success in this matter. To begin with, the Sunday and Saturday collections are under the management of the same Committee, which has for its chairman the Mayor for the time being, and is thoroughly representative, numbering clergy and laity in nearly equal proportions. The former comprise the Archdeacon and Rector of Liverpool, and representatives of nearly all the various sects. Among the lay members are gentlemen who are members of the Committees of the principal medical charities, and three members of our profession (Dr. Steele, Dr. Lodge, and Mr. F. W. Lowndes). The Secretaries, the Revds. W. Banister and Charles Beard, take the greatest interest in their honorary and very arduous duties; and to them and Mr. W. Crosfield, jun., the Honorary Treasurer, much of the success is due. On this latter gentleman devolves the arduous duty of receiving the "advices" from nearly three hundred clergy and ministers, and the counting of the Saturday boxes, in addition to other duties. The daily press cordially aid the movement by drawing the attention of the public to the coming Sunday or Saturday in leading articles; and on the previous Sunday due notice is given by the clergy and ministers in all the churches and chapels that the collections on the following Sunday will be given to the medical charities. Full particulars of each hospital and dispensary are distributed freely among the congregations, and notices posted on all the church and chapel doors. It may be some encouragement to those who find it difficult to establish Hospital Sunday in their midst, to learn that this means of augmenting the funds of the hospitals was only accomplished in Liver-

pool by the most strenuous exertions carried on for years. The difficulties in the case were so great, that they were not overcome till Hospital Sunday had become an institution in all the large and many smaller provincial towns and cities.

#### ELECTRICAL EQUIPMENT OF HOSPITALS.

IT has often been suggested that some means might be adopted by which electricity could be made more readily available as a remedial agent in cases of suspended animation, collapse, and other conditions which are met with occasionally in the surgeries and operating theatres of all hospitals. Arrangements to this effect have been recently carried out in Guy's Hospital, where the two surgeries (male and female) as well as the operating theatre, are brought into continuous connection with the electrifying-room in the centre of the Hospital. In the theatre, the surgeon, in the event of his requiring the agent, has simply to press a small stud, which rings a bell in the electrifying-room, and a simultaneous movement on a numerical indicator shows where the current is required, and not a minute elapses ere the battery is in full operation, the power of the current in the theatre being regulated by the raising or depressing of a metal rod in a glass tube filled with water. In each surgery, in consequence of the absence of the electrician during the night, when the battery is in greater requisition, a somewhat different arrangement is adopted. The current is here placed on by the operator himself by the simple movement of a spring which becomes affixed to a metal button, and the strength of the current is regulated in a similar manner to that in the theatre. Suitable indicating apparatus enables the electrician to discover where the current has been used during the night, and whether it has been left negligently on; and in the daytime, he knows where it is being used, how long it is in operation, and the varying strength of the battery, and whether it requires recharging. The whole apparatus works satisfactorily, and has already been found exceedingly serviceable. Mr. Seymour, the electrician to the Hospital, who has been solely instrumental in carrying out these arrangements, proposes to conduct the currents from the electrifying room to the separate medical wards, so as to obviate the necessity of carrying about his heavy batteries to distant parts of the Hospital.

#### SMALL-POX CASES AT ST. BARTHOLOMEW'S HOSPITAL.

DURING the present prevalence of small-pox in London, and especially in the Eastern districts, it is not surprising to hear that some cases have occurred in our Metropolitan hospitals. The large number of patients and their friends who enter the hospital every week from infected districts must at times bring the danger of contagion. Five cases of small-pox have just occurred in St. Bartholomew's Hospital. These were confined to two of the wards. As soon as the cases were identified, they were removed from the hospital, and stringent measures were adopted for the complete isolation of the patients remaining in these wards, as well as of the nurses and servants there engaged. These restrictions were maintained until the medical staff were of opinion that they were no longer necessary, the visits of friends to the two wards where the outbreak had occurred have been prevented for a few days longer. No fresh cases have occurred.

#### SMALL-POX AT HARWICH.

WE are informed from Harwich that fresh cases of small-pox, at the average of one daily, have occurred there; and, judging from the virulent type of the cases, it does not appear that the epidemic can be said to be on the wane. Out of thirty-nine cases received into hospital, as many as sixteen have been confluent or semiconfluent. Amongst them are included two that come more properly under the class of variola cruenta, where the skin on the face and forehead had a purple hue, as if from effused blood; and, instead of raised vesicles, there appeared rather hyperæmia of the papillæ. So far, there have been eight deaths in the hospital, making a little more than twenty per cent. of those admitted. There appears, indeed, to be only one way of stamping out the disease, and that is by extensive (compulsory)

revaccination. If this be not carried out, an epidemic, which could easily be stamped out in three months, will hang like a pall over the district, perhaps for twelve months to come, not only paralysing trade and commerce, but severely thinning and weakening the population.

#### THE HEALTH OF THE POPE.

A MEDICAL correspondent in Rome informs us that the health of the Pope is as satisfactory as his old age and state of habitual debility can allow. For six weeks he kept his bed, not from actual necessity, his physicians having given advice to the contrary, but because he suffered less pain in his leg when in a recumbent position; and he may be influenced by the knowledge that one of his brothers, who died at an advanced age, remained in bed almost continuously for seven years without detriment to his general health. The mechanical structure of the pontifical couch has been arranged in Paris so that, by means of a system of wheels, he can easily be transported from one place to another; and, by the advice of his attendant, he changes his room more than once a day. His intellectual faculties and spirits have shown no sign of decadence; and, in spite of his advanced age, it is quite possible that his life may be prolonged for some years to come. I am just informed that, following the wish of Dr. Ceccarelli, the Pope has left his bed for some hours. All that relates to the health of His Holiness is enshrouded in mystery.

#### ROYAL EAR HOSPITAL, SOHO.

THE Committee have been during the past year very busy reorganising this charity, which is the oldest special institution for aural diseases, having been founded in 1816. In January last, the vacancy occasioned by the death of the Senior Surgeon, Mr. W. Harvey, was filled by the promotion of Dr. Urban Pritchard, and Dr. Matheson was appointed Assistant-Surgeon. The Committee have now been fortunate enough to secure the services of Dr. Lionel Beale as Consulting Physician, and Mr. John Wood as Consulting Surgeon. The name of the institution has been changed from the "Royal Dispensary for Diseases of the Ear" to the above; and an in-patient department with six beds is to be added, thus supplying a want long felt by the surgeons.

#### THE SOCIAL SCIENCE ASSOCIATION.

AT a recent meeting, this Association considered the question of the water-supply to the metropolis, in regard first to its purity of source, the continuance of its service, the pressure at which it ought to be delivered, and the manner in which it ought to be controlled; when it was stated that of eight leading water-companies of the metropolis, seven obtained their supplies from a sewage-polluted source, the exception being the Kent Water Company.

#### CLINICAL SOCIETY OF LONDON.

THE following is the list of officers and Council for 1878 elected at the last meeting of the Society. The gentlemen whose names are marked with an asterisk (\*) were not on the Council or did not hold the same office during 1877. *President:* G. W. Callender, F.R.S. *Vice-Presidents:* \*Wilson Fox, M.D., F.R.S.; \*S. O. Habershon, M.D.; C. Murchison, M.D., LL.D., F.R.S.; R. Barwell, Esq.; C. Heath, Esq.; \*J. W. Hulke, Esq., F.R.S. *Treasurer:* E. H. Greenhow, M.D., F.R.S. *Council:* H. Charlton Bastian, M.D., F.R.S.; Andrew Clark, M.D.; Thomas H. Green, M.D.; \*Graily Hewitt, M.D.; A. J. Pollock, M.D.; \*J. E. Pollock, M.D.; R. Southey, M.D.; \*H. G. Sutton, M.B.; \*Thomas T. Whiphram, M.B.; C. Theodore Williams, M.D.; Frederick J. Cant, Esq.; \*James G. Glover, M.D.; J. Warrington Haward, Esq.; \*J. Langton, Esq.; W. Mac Cormac, Esq.; Arthur B. R. Myers, Esq.; \*Thomas P. Pick, Esq.; Michael W. Rice, M.D.; Edgcombe Venning, Esq.; \*William W. Wagstaffe, Esq. *Honorary Secretaries:* William Cayley, M.D.; \*F. Howard Marsh, Esq. The annual reports of the Council and Treasurer which were read to the meeting showed that the Society was in a flourishing

condition. Dr. A. P. Stewart and Mr. Spencer Watson moved that the reports be adopted. The motion was carried unanimously. Mr. Maunder and Mr. T. Smith moved a vote of thanks to the retiring Vice-Presidents and members of Council. This was also carried unanimously. Lastly, Mr. Berkeley Hill and Dr. Burney Yeo moved that a special vote of thanks, for his very valuable services to the Society, be accorded to Mr. Pick, the retiring Surgical Secretary. This proposition was carried with marked approval.

#### SUICIDE OF AN ENGLISH DOCTOR.

THE *Globe* states, on the authority of a Russian correspondent, that on the 21st ultimo, as Dr. Radcliffe, who was suffering from mental aberration, was being conveyed from Hassan Voort to Tiflis, under the charge of a Russian military surgeon, he contrived, at the Tsalkanski Station, to effect his escape, and was afterwards found in a retiring room lying dead on the floor. In his hand was found a knife, with which he had almost severed his head from his body. At the official inquiry held on the following day at the Tsalkanski Station, a district doctor stated that, during the *post mortem* examination, he had extracted from the head of Dr. Radcliffe a rifle-bullet, which had penetrated the skull sufficiently deep to cause insanity, though not death. The injury had been inflicted while the doctor was attending the wounded on one of the battlefields of Armenia.

#### THE SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE Quarterly Court of the Directors of this Society was held on Wednesday, January 9th, by the kindness of the Royal Medical and Chirurgical Society, in their rooms, 53, Berners Street. The chair was taken by Dr. Pitman, Vice-President. The sum of £1,238 was voted to be divided, according to their circumstances, among sixty widows; a sum of £55 was distributed to twelve children: and £25:10 was given from the Copeland Fund to four applicants for assistance. The expenses of the quarter amounted to £39:1:3. The Treasurer informed the Court that the Christmas present had been distributed on December 17th among fifty-eight widows and fourteen children, and was received with much gratitude. The amount given was £326. Fresh applications for grants were accepted from two widows and two orphans. Six new members were elected. We may once more call attention to the extremely valuable results achieved by this beneficent Society, and the very small amount of the expenses incurred in distributing the relief granted. Moreover, there is here no loss of interest chargeable to capital sunk in grounds and building, and in salaries of officers necessary for keeping up the same; and, as the whole of the benefits are distributed without the pain, costs, labour, and injustice involved in the canvassing system, we cannot too highly commend this Society to our members. It is a matter of surprise that they do not join it in greater numbers; for, in so doing, those whose means of sustenance hang upon a precarious thread provide for their families some direct claim upon the funds to which many are by the hard strokes of fate unexpectedly compelled to appeal, whilst those who are sheltered from such misfortunes contribute a tax but lightly felt towards funds which are distributed in the most unexceptionable, careful, and economical manner to the distressed widows and orphans of medical men.

#### EXCISION OF THE LARYNX.

THE man on whom Dr. Foulis of Glasgow performed the operation of excision of the larynx, as reported in the *JOURNAL* of December 8th, 1877, was exhibited at the meeting of the Medical Society of London, on Monday evening last. The artificial larynx, devised by Gussenbauer for the subject of Billroth's first operation of the kind, in 1873, was also shown. The apparatus used in Dr. Foulis's case is a modification of that of Gussenbauer. It consists of two tubes, one of which goes downwards to the trachea, and the other upwards to the mouth. The patient, we are informed, can talk in a whisper without these tubes; but when a reed-plate is slipped into a groove in the lower tube,

a resonant sound is produced, which is modulated into letters and words by the mouth. The articulation with or without reeds is perfect. The reeds are made of metal, vulcanite, ivory, horn, etc., and the patient himself is fond of making reeds which give his voice new and surprising tones. The voice is a monotone, varying in *timbre* according to the reed used. The sound-waves of the patient's voice on Koenig's mirror were similar to those of other voices, as was shown by Mr. Ward with a mirror lent by Mr. Spottiswoode. Dr. George Buchanan (the President of the Society), Dr. B. W. Richardson, Professor Lister, and others, spoke very warmly of the results achieved.

#### UNIVERSITY FACILITIES.

THE English medical student is the only student in the three kingdoms to whom the degree of M.D. is made almost inaccessible unless he consent to expatriate himself. We have often pointed out the hardships, and shall not cease to return to the topic until a remedy is provided, that the London medical student, after he has passed through a triple ordeal of examination by the three great licensing bodies of London—the Colleges of Surgeons and Physicians and the Apothecaries' Society—is not entitled to call himself a Doctor, although that privilege is acquired on certainly no more onerous terms, and after no more severe tests of knowledge, by students of Edinburgh, Glasgow, Aberdeen, Durham, Belfast, Cork, Galway, etc. Dr. Charteris of Glasgow, in an address which he gave last November at the Andersonian College, Glasgow, observed that he has heard it stated, as a reproach to that College, that its fees are small, and that it offers a cheap pathway to the profession. He considers this as no reproach. Nay, he deems it an unspeakable boon, as well as a distinguishing characteristic. The lips of the slanderer should be sealed when Andersonian students point to the life of an old Andersonian student. Many years ago, a weaver-boy placed a Latin grammar on the spinning-jenny, and, unmoved by the noise of the machinery and the novelty of the position, learned its rudiments as he passed from loom to loom. The boy grew into a loose slim-jointed lad of nineteen years, and was fired by the innate ambition of his nature to become a member of a profession which, as he expressed it, "is pre-eminently devoted to practical benevolence, and which with unwearied energy pursues from age to age its endeavours to lessen human woe". So he scraped together, by the hard work of his handicraft, what would support him here as a medical student during the winter, by returning in the summer to his loom and his weaver's lot. With justifiable independence and pride, he said, "I never received a farthing of aid from any one". The Blantyre weaver-boy had his ambition gratified by the facilities which the Andersonian College gives, and David Livingstone became the great traveller, the good physician, the Christian missionary; and when, tired and worn with life's journey, he sank to his rest, faithful hands bore him homewards, and a grateful nation placed his remains in that mighty mausoleum where England loves to bury those of whom she is proud.

#### THE PUBLIC HEALTH.

DURING last week, 6,196 births and 4,080 deaths were registered in London and twenty-two other large towns of the United Kingdom. The natural increase of population was 2,116. The mortality from all causes was at the average rate of 25 deaths annually in every 1,000 persons living. The annual death-rate was 28 per 1,000 in Edinburgh, 24 in Glasgow, and 32 in Dublin. Whooping-cough showed exceptional fatality in Plymouth, Birmingham, and Liverpool, and the deaths from scarlet fever were numerous in Manchester. Small-pox caused 35 deaths in London, but not one in any of the nineteen provincial towns. In London, 2,681 births and 1,760 deaths were registered. Allowing for increase of population, the births exceeded by 125, and the deaths by 62, the average numbers in the corresponding week of the last ten years. The annual death-rate from all causes, which in the two previous weeks had been equal to 25.9 and 27.6, declined again last week to 25.7. The 1,760 deaths included 35 from small-pox,

97 from measles, 39 from scarlet fever, 9 from diphtheria, 69 from whooping-cough, 38 from different forms of fever, and 17 from diarrhoea; thus to the seven principal diseases of the zymotic class 299 deaths were referred, against 311 and 292 in the two preceding weeks. The fatal cases of measles, which had been 109 and 104 in the two preceding weeks, further declined to 97, but exceeded the corrected average by 58, including 42 in the South, and 25 in the North groups of districts; 15 occurred in Islington, 8 in Bow and Poplar, 7 in Southwark, and 9 in Camberwell. The 39 deaths from scarlet fever included 19 in North London, of which 7 occurred in Pancras, and 9 in Islington. The deaths from whooping-cough showed a marked decline from the numbers in the two preceding weeks, but included 7 in Islington, 5 in Bethnal Green, 11 in Southwark, and 5 in Deptford. The deaths referred to fever, which had been 41, 36, and 28 in the three preceding weeks, rose again to 33 last week, and were but 4 below the corrected average; 7 were fatal cases of typhus, 19 of enteric or typhoid, and 7 of simple continued fever. The 7 deceased typhus patients had resided in Islington, Hackney, Clerkenwell, St. George's-in-the-East, Bow, Camberwell, and Lambeth. Four deaths were referred to enteric fever in Pancras (of which 3 occurred in Somers Town), 2 in Islington, and 2 in Deptford. Zymotic disease has recently shown exceptional fatality in Islington; and during last week, of 126 deaths registered within this district, no less than 41, or 33 per cent., were referred to the seven principal diseases of this class.

#### LIVERPOOL MEDICAL INSTITUTION.

THE following office-bearers were elected at the annual meeting of the Liverpool Medical Institution, held January 8th, 1878. *President*: Dr. A. T. H. Waters.—*Vice-Presidents*: Dr. Lyster, Dr. Wm. Carter, Mr. Manifold, Dr. Oxley.—*Treasurer*: Dr. Dickinson.—*Honorary Secretary*: Dr. Caton.—*Honorary Secretary of Ordinary Meetings*: Mr. C. Puzey.—*Honorary Librarian*: Dr. Campbell.—*Members of Council*: Dr. Alexander, Dr. Bailey, Dr. Braidwood, Mr. E. A. Browne, Dr. Finegan, Mr. Harrison, Dr. Matthew Hill, Dr. S. Lewis, Mr. McCheane, Dr. Robertson, Dr. Samuels, Dr. Turnbull.—*Microscopical Committee*: Dr. Braidwood (*President*), Dr. Ashby (*Honorary Secretary*), Dr. Davidson, Dr. Glynn, Dr. S. Hicks, Dr. Lupton, Dr. Paul, Mr. Hamilton, Mr. Newton, and Mr. Rushton Parker.

#### SCOTLAND.

THE medical men of the burgh of Kirkcaldy, along with the Hospital Committee of the Local Authority, have had a meeting for the purpose of taking steps for the erection of a hospital for the treatment of infectious diseases. The matter was favourably considered, and there is every likelihood of a hospital being erected.

#### GLASGOW ROYAL ASYLUM FOR LUNATICS.

THE sixty-fourth annual meeting of the subscribers was held last week. During the past year, 751 patients had been treated; of whom 81 had been discharged recovered, 69 relieved, 48 had died, and 553 remained at the end of the year, of whom 198 were private patients and the remainder paupers. There had been 532 at the beginning of the year. The new halls had been finished and opened during the year.

#### SUSPECTED MURDER.

A PROLONGED inquiry has been held during the last week or ten days, in private, by the Procurator-Fiscal of Edinburgh, into a case of supposed wife-murder. The woman supposed to have been murdered was found in a dying state, in a room in which gas was escaping from a hole in one of the pipes. The husband, a teacher of French, has been arrested on suspicion. Beyond the fact that, a short time before the woman's death, a policy of insurance had been effected upon her life, none of the evidence has as yet been allowed to transpire. An

analysis of the contents of the stomach has now been completed in Edinburgh; and, in consequence of a report of Professor MacLagan and Dr. Littlejohn, the husband has been committed for trial on a charge of having poisoned his wife by administering to her chloral and morphia, or one or other of these poisons.

#### THE EDINBURGH INFIRMARY.

At the annual general meeting of the Edinburgh Royal Infirmary, held on January 7th, the report for the past year was read, showing that, during that period, there had been treated in the hospital very nearly 5,000 persons; among these were 109 cases of fever. Of these whose cases terminated during the year were 2,404 ordinary medical cases and 1,945 surgical; 389 persons remained in the house at the date of the report. The highest number in hospital on any one day was 490, the lowest 377; the average time during which each patient remained under treatment was thirty-six days. Above 10,000 out-patients, principally surgical cases, were attended to, receiving all the necessary dressings and appliances at the hospital. The directors reported in most favourable terms of the high state of efficiency of the nursing department; and brought in evidence the fact that they had frequent applications, from all parts of the kingdom, for nurses to fill the position of matron or head-nurse in other hospitals, and for private nursing. The actual cost per occupied bed, including expenditure of every kind, during the year 1876-77, has been £52 6s. 9½d., showing a decrease of fifteen shillings on the corresponding expenditure of the previous twelve months. The building of the new Infirmary was being steadily proceeded with, and it was expected that all the buildings will be ready and complete by the summer of 1879. Upwards of £200,000 had already been expended on the new buildings, and it was estimated that about £130,000 would be required to complete them.

#### UNIVERSITY OF EDINBURGH.

THE matriculation returns for the past year have now been completed, and show a considerable increase in the number of students in residence over any former period. The number on the register for 1876 were 2,302; for 1877, they amounted to 2,560. In the Faculty of Medicine there were 1,176, by far the highest share, the next being the Faculty of Arts, with 953. In the medical faculty, the wide range of supply of students is as remarkable as in former years, and shows how largely our Colonies and India are availing themselves of the special educational forces of this country. Of the 1,176 students of medicine, 521 are from Scotland, 407 from England, 20 from Ireland, 133 from the Colonies, 65 from India, and 28 from foreign countries. In the list of graduates during 1877, are 7 who took the degree of D.Sc. and 17 that of B.Sc., of whom three of the former and four of the latter were in the department of public health. In medicine, 34 took the degree of M.D., 109 that of M.B., and 101 that of C.M. The ground is now being cleared for the erection of the University Extension Buildings, which, with the aid of the Government grant—the first instalment of which, viz., £20,000, it has just been intimated, is to be inserted in the Estimates for next year—will be vigorously proceeded with, so as to furnish as soon as possible the additional accommodation urgently required for the increasing number of students, and for the fuller development of the teaching resources of the University.

#### AN EPIDEMIC TRACED.

DR. RUSSELL has just published a brilliant report on the epidemic of enteric fever, which has been prevalent in the west end of Glasgow and the west end suburbs of Hillhead. He traces the steps by which he pursued the inquiry into the source of the infection, and no one can read his report without being convinced that here again we have an epidemic traceable to infection through milk. We shall tell the tale, not as Dr. Russell does, but rather in the order of time, and with all possible brevity. In a picturesque situation, on the banks of the Avon, stands a farm, whose arrangements are such as to favour the contamination of the products of the dairy. In this farm a son sickened with en-

teric fever on December 1st, a servant girl on December 20th, and another boy on December 27th. The work of the dairy was carried on by persons who attended the patients. From this farm there were sent daily twenty-five gallons of milk to Messrs. Semple and Wilson of Hillhead, and they passed on eight gallons to Messrs. Morrison. The seventeen gallons retained were distributed to families in Hillhead and the west end of Glasgow, partly to wholesale and retail customers. The immediate result was an epidemic of enteric fever, almost entirely among the customers of Messrs. Semple and Wilson and Messrs. Morrison. The manner in which the disease picked out the persons using infected milk is most graphically shown, by one or two examples appended, by Dr. Russell, which we may quote.

"In Hill Street (Garnethill) there are seven families supplied with suspected milk, of whom three are infected, and a hundred and eighty-one supplied otherwise, not one of whom is infected. In Berkeley Terrace there is one family supplied with suspected milk, which is infected, and thirty-seven otherwise supplied, not one of whom is infected. In Royal Terrace there is one family supplied with suspected milk, which is infected, and twenty-eight which is otherwise supplied, not one of whom is infected. In Lynedoch Crescent there are two families supplied with suspected milk, of whom one is infected, and fifteen otherwise supplied, not one of whom is infected. In Park Street East, there are five families supplied with suspected milk, of whom one is infected, and twelve otherwise supplied, not one of whom is infected. In Park Circus there are nine families supplied with suspected milk, of whom two are infected, and twenty-seven otherwise supplied, not one of whom is infected. In Woodlands Terrace, there are seven families supplied with suspected milk, of whom five are infected, and fourteen supplied otherwise, not one of whom is infected. In Park Gardens two families are supplied with suspected milk, one of whom is infected, and four supplied otherwise, not one of whom is infected. In Clairmont Terrace there are seven families supplied with suspected milk, of whom three are infected, and five supplied otherwise, not one of whom is infected. In Woodside Crescent there are four families supplied with suspected milk, one of whom is infected, and thirteen supplied otherwise, not one of whom is infected. Another area of infection is amongst the students of the University, who, on the 21st December, were dispersed over the country for their Christmas holidays. There are now some absentees from illness, and I have obtained the names of seven of these who have already been discovered to have enteric fever. Of that small number three are now dead—at Kilwinning, at Langloan, and in Islay. The refreshment room in the University was supplied with milk by Semple and Wilson. It was largely patronised by the students, and those men are known to have partaken of the milk."

Dr. Russell may well remark that, in this epidemic, we have as clear an experiment performed for us as in any of the demonstrations of the chemist's laboratory.

#### IRELAND.

At the Belfast Police Court, last week, Dr. Owen O'Hare of Castle Street, to whose case we recently referred, was sent for trial to the spring assizes, on the charge of forgery and obtaining money under false pretences. Bail has been refused, the charge being a serious one.

AN election for medical officer for Oola Dispensary, in the New Pallas district, took place last Monday, when Dr. Ryan of Scarleen was appointed by a majority of four votes. A large force of constabulary and two troops of dragoons were sent by an early train to the locality, in consequence of a riot which occurred at the same place some years ago during a dispensary election; but fortunately their "services" were not required.

#### THE LATE DR. STOKES.

THE funeral of this eminent physician took place on the 11th instant. In accordance with the wishes of the family, the ceremonial was of a private character. Notwithstanding, a large number of his former professional and private friends were present on the occasion in the quiet little country church-yard of St. Fintan's, in Howth. As a token of

the universal respect in which Dr. Stokes was held, his coffin was borne the short distance which intervened from his house to the entrance of the graveyard on the shoulders of some of the labourers living in his neighbourhood, in front of the hearse. From the gate, a selected few of the students of the Meath Hospital—who attended in a large body—carried the remains of their former beloved and illustrious teacher to the grave. The Royal Irish Academy, of which Dr. Stokes was an ex-President, and the Governors of the Meath Hospital, have adopted resolutions expressive of their sincere sorrow at his death, and tendering their condolence to his family. It is generally believed that Dr. Banks, Physician to the House of Industry Hospitals, and formerly King's Professor of the Practice of Medicine in the School of Physic, will be chosen to succeed Dr. Stokes as Regius Professor of Physic in the University.

#### OVARIOTOMY.

THIS operation was performed in each of the two Lying-in Hospitals of Dublin last week. Both cases were considered unfavourable ones for operation. The patient operated on in the Rotunda died on the second day.

#### DONATIONS TO DUBLIN HOSPITALS.

SEVERAL of the Dublin Hospitals have received, within the last week, considerable sums of money from the Misses Brooke, sisters of the late John Brooke, Esq., Q.C. These charitable ladies have given, among other donations, £1,000 to the Adelaide Hospital; £600 to Stevens's Hospital and the National Eye and Ear Infirmary respectively; and £200 each to Sir Patrick Dun's, the Meath, Mercer's, and the Rotunda Lying-in Hospitals.

#### DUBLIN HOSPITAL SUNDAY FUND.

THE annual meeting of the friends and supporters of this fund was held on Tuesday last. From the report of the Council presented to the meeting, it was satisfactory to find that the number of collections made during the year (1877) showed an increase of 21, as compared with the previous year, and that the total amount collected—£4,143 19s. 6d.—was £270 10s. 3d. over last year. The average amount collected from each congregation has also showed a steady annual increase. For the first time since the institution of the Hospital Sunday collection in 1874, there has been a falling off this year in the gross receipts from subscriptions by the participating institutions. But this may be attributed to the causes which have produced a similar result in the case of the public charities of the United Kingdom. After deducting the very moderate working expenses, and placing a sum of £153 18s. 4d. to the credit of the fund for next year, a sum of £3,900 remained in the hands of the Committee for distribution among the fifteen hospitals participating in the fund. This sum was awarded as follows:—Sir Patrick Dun's, £200 11s. 9d.; City of Dublin, £557 18s. 2d.; Stevens's, £85 17s. 7d.; Meath, £444 19s. 6d.; Mercer's, £208 0s. 9d.; Whitworth (Drumcondra), £70 8s. 11d.; Coombe (Lying-in), £142 16s. 9d.; Rotunda (Lying-in), £235 14s.; St Mark's (Ophthalmic), £184 2s. 4d.; National Eye and Ear Infirmary, £68 10s. 5d.; Convalescent Home, £347 2s. 10d.; Cork Street (Fever), £186 18s. 7d.; Adelaide, £659 6s. 9d.; less £37 5s., proceeds of a charity sermon, deducted under rule 9; Rathdown (Monkstown), £147 17s. 10d.; Orthopaedic, £269 13s. 2d. Total, £3,900. The mode in which the distribution for each hospital is made is by dividing the fund into thirds, and allotting two-thirds according to the amount of voluntary contributions received by the hospital during the year, and the remaining one-third according to the number of beds maintained by such contributions.

#### THE DISEASED MEAT QUESTION.

WE are glad to learn that the Corporation of Dublin, as the authority for the city, have, in consequence of a suggestion of Dr. Cameron, their Medical Officer of Health, adopted a resolution to the effect that, in view of the unsettled state of scientific opinion as to the fitness of the

flesh of animals affected with pleuropneumonia for human food, the Government be requested to issue a Commission to inquire into the whole subject, with a view to a more uniform administration of the law bearing upon this important question. Dr. Cameron has recently published an able Report on the Use of the Flesh of Animals affected with Contagious Pleuropneumonia as Food for Man (*Dublin Medical Journal*, November, 1877), which has been adopted and circulated by the Public Health Committee of the Corporation. In this report, Dr. Cameron has collected a large amount of professional opinion in favour of and against the use of pleuropneumonic meat as food, in different stages of the disease; and as, under the Animals' Diseases Act of 1876, 1,100 beasts have been slaughtered in the two Dublin Unions in a period of barely twelve months, at a very large pecuniary outlay, it is important for every reason to have the question finally decided, if possible, by a competent Commission.

#### THE HIGH DEATH-RATE OF DUBLIN.

THE deaths registered in the Dublin district during the week ending January 12th, 1878, represented an annual mortality at the enormous rate of 31.7 in every 1,000 of the population. In London, during the same period, the death-rate was 25.6 per 1,000. Of the 36 deaths registered in Dublin during the week from zymotic diseases, 26 were amongst children under five years of age; measles and whooping-cough being the chief assignable causes. Fifty-six deaths resulted from diseases of the respiratory organs; being an increase of 7 over the average number of deaths from such causes in the second week of the year for the last ten years. The number of deaths registered in the Dublin district during the last quarter of the year 1877, was 2,102; being equal to an annual ratio of 27 per 1,000.

#### DEPORTED PAUPERS.

AN inquest recently held in Dublin again calls attention to the unsatisfactory condition and laxity of administration of the law which is supposed to regulate the removal of persons of Irish birth who happen to become paupers in England. The following is the brief but dismal history of Michael Kenny, aged 35, who died in the South Dublin Union Workhouse on January 3rd. The deceased was admitted to the Brownlow Hill Union Workhouse in Liverpool, and on October 10th, was placed under medical charge, as he was suffering from chronic pulmonary disease, which proved to be phthisis. He was placed in the Workhouse Infirmary, and no substantial change took place in his condition up to November 16th. The medical officer declared that at this time, or rather on November 10th, when he examined him, he considered him unfit to be removed to the "healthy wards" of the workhouse; yet on November 16th, he was sent as a deck-passenger to Dublin, in company with another pauper just removed from the infirmary, two other apparently healthy paupers, and a little girl (said to be only four years old). Kenny, on his arrival in Dublin, was found to be so ill that he was at once removed to the Workhouse Infirmary, where he remained confined to bed until the day of his death. On the day before his death, Kenny cut his throat, and declared that he did so to terminate his sufferings, which he said had been aggravated by his voyage from Liverpool; hence the inquest. The only excuse urged by the Liverpool officials was that Kenny had not complained, and had signed the official form consenting to his removal; that he had got hot coffee and some food on board ship. This is all very plausible, but in no way excuses the barbarity of permitting, not to say compelling, one convalescent pauper, one dying pauper, and a helpless little girl, to pass the night on the deck of a steamer, even with a "hurricane-deck", in the middle of November. Some of our readers know what the decks of the splendidly formed *Holyhead* and *Kings-town* steamers are on a wet and windy November night, and must shrink with horror at the thought of poor Kenny with only the "hurricane-deck" to shelter his weak and wasted frame. We trust some of the Irish members of Parliament, who talk so loudly of imaginary political grievances, will see to this real grievance.

## ON THE APPOINTMENT OF CORONERS; THEIR QUALIFICATIONS AND DUTIES.

THE following important further memorandum has with great kindness been prepared by Dr. Alfred Swaine Taylor, F.R.S., for the use of the Parliamentary Bills Committee. We invite comment upon it.

1. In a former paper, suggestions were offered for the improvement of medical evidence at coroners' inquests by the appointment of a skilled expert to conduct the *post mortem* examination, and of an analyst to make an analysis when required.

2. These suggestions admit of being carried out more or less, wholly irrespective of any change in the mode of electing or appointing persons to the office of coroner.

3. It seems desirable, however, that the rules and regulations now in force regarding this office, should undergo a complete revision, and, with this view, the following additional suggestions are submitted for consideration.

**QUALIFICATION AND APPOINTMENT OF CORONER.**—4. The duties of the office of Coroner should be limited to inquiries into the causes of death in all cases in which there is reasonable ground to believe that the deceased person has not died from natural causes; or there is reasonable ground to suspect that his death has been accelerated or caused by violence of any kind. We are told by authority that, "in his judicial capacity, a coroner has to inquire when anyone comes to his death suddenly or violently, and how and by what means such death was caused". His inquiry should extend also into those cases in which persons are found dead, and nothing is known concerning them.\*

5. From the nature of these duties, it will surely be admitted that no person should be appointed to the office of coroner until he has undergone some test of his qualifications to perform the duties thereof.

6. Registered members of the medical profession, solicitors, and barristers of a certain number of years' standing, should be eligible as candidates for this office.

7. All the Acts for appointing coroners by charter, or election by freeholders of the county, should be repealed or consolidated into one Act, with new provisions for the appointment of fit and proper persons to the office. The election of coroners by the votes of freeholders dates from the 3 and 4 Edward I (A.D. 1275), about six hundred years ago. Other Acts on the election of these officers have been since passed—e.g., the 28 Edward III, 38 George III, c. 95; 7 and 8 Victoria, c. 92; 6 and 7 Victoria, c. 12. Such a mode of electing a man to a judicial office requiring a knowledge of the law of evidence and, in a medical point of view, an acquaintance with the ordinary causes of sudden and violent death, is a perfect anachronism unworthy of the age in which we live, and conflicting with all modern legislation in reference to other judicial offices.

8. Records of boroughs, stipendiary magistrates, and County Court judges are not elected to their offices by the votes of county freeholders, but according to their merits; they receive their appointments by nomination from the law-officers of the Crown, or from the hands of men well qualified to judge of their fitness for the office.

9. Under the present mode of county election, the editor of a newspaper, an auctioneer, land-agent, house-agent, or a retired tradesman, provided he renders himself popular with the freeholders, may be elected to the office of coroner, although quite incompetent to perform its duties. The election system for counties is objectionable under another point of view. It has thrown a great expense on many of the candidates. In an opposite election, committees are appointed, committee-rooms hired, hustings erected, public-houses retained for voters, and votes are obtained by bribery and corruption. In fact, at these elections, an office for conducting inquiries into the causes of death is

put up to a sort of auction and is knocked down to the highest bidder.\* It is a bad copy of the Parliamentary mode of election.

10. So long as the election system of appointment continues, there can be no hope of substantial reform or improvement, since there can be no guarantee that a properly qualified person will succeed in obtaining the office.

11. As the appointment by election carries with it no test of competency, it is not surprising that inquests are often ill-conducted. There are mistakes in holding inquests in cases in which none are required, or in not holding them where they are really necessary; there are mistakes in the reception of evidence and in the verdicts of juries, and, finally, such errors of omission or commission in the drawing up of depositions that, in every case of great public interest, a magisterial inquiry generally follows. At this inquiry, the same witnesses are again examined in proper legal form, and it is upon these depositions before the magistrates, and not upon the verdict of a coroner's jury, that an accused person is subsequently tried.

12. A medical man without any knowledge of the law of evidence, and a barrister or solicitor in entire ignorance of the ordinary causes of sudden and violent death, are equally at fault, and are out of place in the office of coroner. There is special knowledge required, and of the possession of this a man should, it is submitted, give some proof before he is allowed to act as coroner. Persons are not admitted into the army, navy, or civil service, for the performance of duties of great responsibility, and affecting the public interest, until they have given some test of their competency by examination; and, if we desire to exclude ignorant and incompetent persons from the office of coroner, the examination system should be applied to all who seek this office.

13. An examining board for this purpose might be easily constituted by the appointment of three qualified examiners: a barrister of seven years' standing, a professor of medical jurisprudence or forensic medicine of similar standing, and a lay member selected from educated men of the middle or upper class. This board of three members should have the power of deciding whether the candidate (6) is or is not qualified for the office.

14. Although it might be thought desirable, for obvious reasons, to confine the office of coroner to registered or admitted members of the legal and medical professions, this scheme need not exclude any qualified men who can pass the examination, and satisfy the examiners of their competency to perform the duties of the office.

15. Those candidates who can produce certificates of having passed

\* When the subject of coroners and their inquests was brought before the House of Commons in July 1876, Mr. Secretary Cross stated that "there were instances without end of enormous sums of money being spent in order to secure the election of a coroner". Mr. Cole said that some elections had cost as much as from £10,000 to £12,000. The election of a popular candidate for this office for one division of Middlesex many years since is reported to have cost the candidate or his friends £7000. It is impossible that such sums as these can be expended in any lawful charges. This fact alone is sufficient to deter many competent men from offering themselves as candidates. The inconsistency and absurdity of this mode of election will be further apparent from the fact, that the thousands of educated leaseholders, annual tenants of houses, and lodgers in a vast borough like Marylebone, have no vote in the election of a coroner for this division of Middlesex. The coroner, however, when elected, claims an equal right to hold inquests on the bodies of the leaseholders and lodgers after death. A writer on this subject truly says, that "the qualification of the electors is such as to secure the exclusion from the constituency of those persons who may be most likely to form a competent opinion of the merits of the candidates in relation to the requirements of the office. The owner of the site of a property may be a voter, while the occupier of an estate may have no voice in the election."

† It is a common opinion that the office of coroner should be occupied exclusively by members of the legal profession. I cannot assent to this view. A coroner should undoubtedly be well acquainted with the law of evidence and the mode of examining witnesses, so as to elicit the truth; but the acquisition of this legal knowledge is not beyond the capacity of a well educated medical man. Promptness of decision, tact, and discretion—qualities most necessary to a coroner—may be met with in both professions. A legal coroner, who has no knowledge of forensic medicine or medical jurisprudence, will be unable to distinguish between cases which require, and those which do not require, an inquest. Unless he know something of the various causes of sudden death, and the circumstances by which sudden death from disease may be distinguished from sudden death by poison or violence, he will be unable to make any safe distinction between them. Without some medical knowledge, he cannot arrive at a correct conclusion on this important point. In holding an inquest, he will always be liable to misunderstand the medical facts put before him. He will not be able to distinguish the true from the false, to detect errors in medical evidence, or to determine the relative value of the medical opinions. Some amount of medical knowledge is undoubtedly required for the efficient performance of a coroner's duties. It will not only enable him to sift cases with judgment before entering an inquest, but to put proper questions to medical witnesses and arrange and arrange the medical facts in an intelligible form for the consideration of the jury. If he know something of the hydrostatic test as applied in infanticide, of the properties of the drugs used in criminal abortion, or of the detection of poisons upon clothes and weapons, this knowledge will enable him, in the event of a fatal case, to point out to a jury the most trustworthy evidence. Intelligent men appointed to the coronership under existing rules acquire this knowledge in time, but there is no reason why a coroner should not start with it. The true causes of death are sometimes overlooked by medical witnesses in making an inspection of the body. A medical coroner has been able to make a suggestion as to parts of the body left unexamined, which a purely legal coroner would have thought necessary, and thereby to determine the cause of death, and save an innocent man from a charge of manslaughter.

\* The time has arrived when the jurisdiction of the coroner should be completely separated from that of the magistrates in petty sessions, so that there should be only one public investigation instead of two. The coroner's duty should be simply a preliminary inquiry, limited to determining the cause of death, with a power of committing for examination before the magistrates in petty sessions any person to whom the verdict may point as being probably guilty of a criminal act. Magistrates in petty sessions can only take cognisance of a charge against an accused person; and here a public prosecutor is required, in order to prevent the failure of justice. The action of the coroner should be as soon after the death as possible, and the magistrates should deal with the case only after this preliminary inquiry by the coroner. The commitment of an accused person for trial should rest entirely with the magistrates and not with the coroner. This office has no right or power to have the accused before him; and it is contrary to the spirit of English law to take evidence against an accused person in his absence. The depositions taken before a coroner should be used only to establish the cause of death. Those taken before the magistrates, under strict legal rules, should alone be used at the trial of the accused.

this examination should be considered eligible for the office of coroner on any vacancy occurring. The appointment might be made from among such candidates by a board of county or borough magistrates nominated or selected for that purpose. The appointment of the selected candidate should receive (if considered necessary) the sanction of the Secretary of State for the Home Department.

16. The candidates so appointed should hold the office of coroner on the rule *quandiu se bene gesserit*. On proof of malversation, neglect of duty, or improper conduct, it should be in the power of the board of magistrates who appointed him, to remove him at once from the office by summary process, and to appoint another in his place. The removal should lie with the sanction of the Secretary of State for the Home Department.

17. The present county and borough coroners should retain their offices and emoluments, except where it may seem desirable to superannuate them, or allow them to retire on a pension. According to a statement made in the House of Commons (July 1876), there were at that date, in England and Wales, three hundred and thirty-two coroners; viz., two hundred and thirty-three county and ninety-nine borough coroners.\* On the average rate of mortality, these numbers would not lead to more than nine vacancies *per annum*.

18. The emoluments of the newly appointed officers to be similar to those of the present coroners. This officer should, in all cases, be paid by a fixed salary, and not by a fee for each inquest. The latter mode of payment, which is still prevalent in boroughs, offers a direct premium upon the holding of unnecessary inquests with the attendant expenses.

INQUESTS.—19. It is not easy to describe or define all the cases in which inquests are required, or in which they should be held. Experience, however, has clearly shown that we cannot trust to the discretion of one man. The indiscriminate power which is now allowed by law to an English coroner to hold inquests on his own arbitrary will, has led to great abuses, and offers no security to the public. Unnecessary inquests are held; the feelings of private families, and even public decency, are outraged upon the most trivial grounds; and the result of the inquiry has, of course, been what any qualified man might have anticipated from the first, "Death from natural causes".

20. In Scotland, the practice is different, and such indecent exhibitions as those above referred to could not occur in that country. The Procurator-Fiscal is an officer appointed by the sheriff for each county. He is always a member of the legal profession, and it is his duty to inquire into every case of suspected crime and into all sudden or suspicious deaths. This inquiry is made in private from information supplied by the police or any other source. If he find that the death was due to natural causes, there is an end of the matter. If otherwise, he procures a warrant for the apprehension of the suspected person, and the case proceeds before a magistrate. The Procurator-Fiscal, who acts like a public prosecutor, in cases in which he deems it necessary, can procure orders for a *post mortem* examination and an analysis. On the necessity for these proceedings, he consults with competent medical men. There is a further protection for an accused person. The whole of the depositions drawn up by the Procurator-Fiscal are finally submitted to the Lord Advocate or one of his deputies, and the proceedings are either quashed or the accused is sent to trial.

21. It will be perceived from this statement that the feelings and reputations of the relations of the deceased, are not outraged by a public inquiry in a case of death from "natural causes". In cases obviously of death from apoplexy or diseased heart, an inquest carried on *ab initio* by the English coroner in opposition to the wishes of the relatives of the deceased is not only painful to their feelings, but may prove injurious to their reputation and prospects. It has been justly said of this indiscreet mode of proceeding that, "if you once give the public leave to suspect, it will be sure, with or without reason, to fasten the suspicion on some one". Every unnecessary inquest may give rise to these unjust suspicions. It would be a good rule to lay down that an English coroner should not be allowed to issue his precept for

holding an inquest until after a consultation with the medical officer of health for the district, and receiving from him a certificate that an inquest is necessary. This would be, as in Scotland, a proper protection to the public. It is not to be supposed that the medical officer of health would connive at the concealment of any suspicious death, and he would not allow any simple case of apoplexy or heart-disease to be treated in the same way as a case of suspected poisoning.

22. In many cases, under a properly qualified coroner, a jury would not be required. In those cases, however, in which the cause of death has not been certified by a medical man, or when the evidence is likely to be conflicting, or where a person has been found dead, and there is no direct evidence of the manner in which he came by his death, it would be proper to have a jury; but this should be limited to five of the parishioners or neighbours. The County Court number would be sufficient in all cases. The present system of summoning twelve, fifteen, or twenty of the neighbours, with the condition that twelve must agree in a verdict, is cumbrous and unnecessary. The agreement of five upon the facts would reasonably suffice for all the purposes of the agreement of twelve. The presence of a jury is a check on the proceedings of an inquest. It will insure publicity to the proceedings; it will prevent the concealment of facts or the misrepresentation of evidence, and it will satisfy the public that the case has been duly investigated. Jurors are justly considered as "important protections against arbitrary convictions, and valuable checks upon overweening judicial authority".

23. In what cases should inquests be held? A large expense is now thrown on counties and boroughs by the holding of unnecessary inquests. Some coroners are disposed to act strictly upon the rules laid down six hundred years ago, and they carry their inquiries into all those cases pointed out by the statutes of Edward I. These include all violent deaths, all casualties by which death ensues, all sudden deaths, persons found dead, persons dying in prison, lunatics who die by suicide, and felons of themselves (Baker on Coroners). Modern legislation has added another to this list; namely, criminals executed in prisons. The most serious abuses have taken place with regard to *sudden deaths*. There are many sudden deaths obviously due to natural causes, and these are in general easily recognisable by a medical practitioner. Except under circumstances elsewhere mentioned (4), such cases demand no inquiry beyond that of the registrar of deaths. Yet, of the thirty-five thousand inquests annually held in England and Wales, these cases form, there is reason to believe, a very considerable proportion.\* *Post mortem* examinations have been made, the feelings of relatives have been shocked by these unnecessary and inquisitorial proceedings, and the result has been what any man with a slight amount of medical knowledge might have predicted, a verdict of death from natural causes. This *nimia diligentia coronatoris* has given rise to scandal on recent occasions in some conspicuous cases, and has led to severe public censure. A well qualified coroner would always act upon the spirit, and not upon the letter, of the ancient statute. On good legal authority,† it is stated "that it is not in every case of *sudden death* that the coroner is justified in holding an inquest, but only where there are grounds for supposing that the deceased died by a death other than natural".

24. This very plain and simple rule, according to my observation, is almost universally neglected. A coroner, whether medical or legal, seems utterly to forget that sudden death, as understood in the reigns of Edward I and Edward III, required a kind of investigation no longer necessary in modern times. To quote the words of an anonymous writer on this subject, "we are no longer so ignorant of disease, no longer so unfamiliar with pathology, as to regard all sudden deaths as suspicious. It is doubtless true that long previous illness is some evidence that death was due to natural causes, but it is not conclusive evidence; for certain poisoners, such as Palmer and Pritchard, have so administered the drugs which were ultimately used to cause death as to produce symptoms closely resembling those of ordinary disease. But, although previous illness is some evidence of death from natural causes, it would be absurd, in the present state of medical science, to say that the mere suddenness of a death, or the mere absence of symptoms previous to its occurrence which were palpable in-

\* From the statements made in Parliament (July 1876), it appears that out of the 233 county coroners, 175 were elected by freeholders; but they were so unequally distributed, that, while Dorsetshire had seven, Middlesex had only five; and, while the populous towns of Liverpool and Manchester had one each, the borough of Malmesbury had two. There are seven different coroners for Norfolk and five for Suffolk, in addition to borough coroners for a number of towns in both counties. Of the Suffolk coroners, one was an auctioneer, another a land-agent, a third a doctor, a fourth calling himself a gentleman, and there were two or three others who were lawyers. It was recently stated in this JOURNAL that in the county of Kent there were no fewer than twenty-two coroners in addition to five deputy coroners. In two boroughs in this county the mayor, on his election, becomes a coroner *ex officio*!—the legal qualification for counties is the possession of a certain amount of landed estate. This may be temporarily given to the candidate, and surrendered by him immediately after election.

\* Mr. Sergeant Cox estimates that four-fifths of the inquests held by coroners, under a proper preliminary inquiry like that adopted in Scotland, would be proved to be unnecessary. Judging by the number of verdicts of death from "natural causes", it is not improbable that the number of inquests not strictly necessary might be taken at one-half. In the autumn of 1874, the Manchester Watch Committee reported to the City Council that in Manchester alone, between 1863 and 1873, inquests were held in 3505 cases, in which the juries found that the persons had died from "natural causes". It cannot be doubted that in a large proportion of these cases a skilled assessor or medical officer of health, under a proper preliminary inquiry, would have pronounced that an inquest was not required.

† Sewell, *Law of Coroner*.

indications of disease to unprofessional observers, was of itself a legitimate ground for suspicion, or a sufficient reason for holding an inquest". Dr. W. Farr, writing on the causes of death in the annual report of the Registrar-General for 1872, says: "The mere fact that death is sudden is a ground for medical inspection, but not necessarily for an inquest; and there are many violent deaths of which a medical inspection may ascertain the cause without moving the apparatus of the inquest, there being no more suspicion of crime in such cases than there is in deaths from fever, pleurisy, or consumption."

25. In order to guard against abuses in this direction, the medical officer of health for the county, district, or borough should be empowered to make inquiry in all cases of death, whether sudden or slow, of all fatal accidents and casualties, and certify to the coroner whether there are any suspicious or unexplained circumstances to justify the holding of an inquest. Under the present state of things, information is generally procured through a parochial beadle. This duty would, however, be better performed by the police.

26. If the medical officer of health have himself attended the deceased person, the officer of a neighbouring district might be substituted. If a medical coroner have attended a deceased person, then the necessary duties of his office should be entrusted to the coroner of an adjoining district. But it would be most desirable that both these officers should be sufficiently remunerated to allow them to abstain from private medical practice.

27. With respect to the coroner, whether he be a member of the legal or of the medical profession, he should, in all cases hereafter, be compelled to resign his practice on his appointment. As a solicitor, he may be required to prosecute, on a charge of murder, a person whom he has committed on the verdict of a jury; and as a medical man, he may have attended the deceased, dying from fatal personal injuries, and be called as a witness for the prosecution, in a case in which he has already acted judicially. These evils may be avoided by assigning a certain district or circuit to each coroner sufficient to give him full occupation, and to compensate him for loss of practice. (The circuits assigned to county court judges may serve as a precedent for this arrangement.)

28. *Super visum Corporis*.—The view of the body at the same time by coroner and jury, now strictly enjoined by law, is an unnecessary proceeding; and when the inquest is on a body exhumed after many months' or even years' burial, it is, according to my observation, both a painful and disgusting spectacle. It is a useless form, but is so strictly adhered to by some coroners, that in the case of the late Sir Charles Lyell, the leaden coffin which was known to contain the body, and which had been soldered down, was cut open in order that the coroner and jury might take a view of it in accordance with the terms of the ancient statute.\* The identity of a body might in any case be easily proved by the oral testimony of witnesses, by a certificate from the registrar of deaths, or, if no inquest can be held except upon the whole or part of a human body, the view of the remains might be taken by the coroner or medical officer of health.

29. Inquests should not be held in private houses, or in public-houses or taverns. In reference to the use of private houses, the first inquest in the Bravo case, shows how easily a great crime may thus escape public notice. Such a practice may lead to the concealment of crime. On the other hand, it may be highly objectionable to the feelings of relatives. Public-houses and taverns are places wholly unfitted for conducting such inquiries. The village or district schoolroom, or a room specially set aside for the purpose, should be selected. Many difficulties in this respect will be removed when it is no longer made imperative on the jury to view the body.

30. *Mortuaries* for the reception of bodies should in all cases be provided in parishes or districts where such an arrangement is possible. In boroughs, there would be no difficulty in establishing a court for the coroner.

31. In the event of an inquest being imperfectly conducted, owing to the rejection of medical or other evidence, provision should be made

\* Under an order of the Secretary of State, I was present at the exhumation of the body of a man six months after death. The coffin was raised from the grave in a country churchyard, and placed by the side of the grave. The lid of the coffin was removed, and fetid effluvia with ammonia copiously escaped from it. The jury (about fifteen in number) stood at a distance of several yards with handkerchiefs to their faces; some rushed up to the grave and took a momentary view. All that they could see was the collapsed face of the corpse, discoloured by putrefaction, and a shroud covered with white and blue mould. This was considered to be such a legal view as the ancient statute requires! No one could identify the body from the features. The carpenter who made the coffin was able to depose that he had placed the body of deceased in the coffin in that grave. Surely this might have sufficed for all the purposes of identity, without requiring the jury to be present at such a spectacle. In order to destroy the effluvia, a quantity of chloride of lime was thrown over the remains in the coffin. This had a temporary effect, but a thick white cloud resembling smoke (sal ammoniac) suddenly issued from the coffin. After this, none of the jury would approach, but all of them in a body precipitately left the churchyard.

by some simple process on application to a superior court for the holding of another inquest by the same or another coroner. It has been suggested that for the reopening of an inquiry, application should be made either to the Home Secretary or the Lord Chancellor, and that it should rest upon either of these ministers to decide upon the necessity of such a proceeding; further, that it should be in the power of either of them to order an inquiry to be made by a coroner in cases in which this officer has declined to hold an inquest, but in which the circumstances may be such as, in their judgment, to justify inquiry. At present, there are many difficulties in the way of reopening an inquiry before the coroner which has once been closed. This was shown in the Bravo case.

32. In the event of a number of persons perishing by a common calamity, as by drowning, shipwreck, suffocation, explosions in mines, or by the bursting of steam-boilers, it should suffice that an inquest, if considered necessary, should be held on one body which could be identified; and if the locality of the accident be one of divided jurisdiction, the inquest on one body, and by one coroner, should suffice for all other bodies and other coroners who might claim a legal right of inquiry. The district in which the body is found dead, wherever the fatal injury may have been received, should be the place in which the inquest is held, and the coroner of that district should be the proper officer to conduct the inquiry.

33. In cases in which a deceased person has been attended shortly prior to death by a registered medical practitioner, and an inquest is considered necessary, that practitioner should be summoned to give evidence of the cause of death. If he be not able to give this evidence in the absence of a *post mortem* examination, it should be for the coroner, with the advice of the medical assessor or medical officer of health, to issue an order to the medical attendant, or any other local practitioner, to make the requisite examination and give evidence thereon.

34. It should, however, be always in the power of the coroner, by and with the advice of the medical assessor or medical officer of health, to call in the aid of a skilled *post mortem* examiner, and assign the examination of the body to him, in place of the local practitioner or practitioners; the examiner so selected to draw up a report of the appearances and his view of the cause of death, and to give oral evidence thereon at the inquest.

35. In any case in which a chemical analysis is required, not merely of the stomach and intestines and their contents, but of the liver and other organs of the body—of suspected blood-stains on articles of clothing, on weapons, or furniture, the coroner should be empowered, by and with the advice of the medical assessor or medical officer of health, to place such articles for examination and report in the hands of a competent and skilled chemist, who should be required to attend before the jury if, in the opinion of the coroner and assessor, such attendance is necessary, and give oral evidence on the results of his analysis.

36. The fee to be paid to the *post mortem* examiner and the skilled chemist should be respectively from three to five guineas each, provided these gentlemen are not paid for such services by fixed salaries. The coroner should be empowered to pay or issue an order for the payment of these fees at the termination of the inquest. Local practitioners should receive the fee now awarded, namely, one guinea for attendance and evidence, and two guineas in those cases in which they have been required to make a *post mortem* examination.

37. Any medical man making a *post mortem* examination in a case intended for an inquest, without a legal order from the coroner, should receive no fee for such examination; and no order of the coroner should be valid except that which has been issued in due legal form, according to the schedule of the statute, before the examination is made.

38. Any general orders issued by coroners to certain medical men in a district to make *post mortem* examinations without the proper warrant signed by the coroner, under the schedule of the Act, should be invalid and of no effect. A coroner must in no case delegate his power of selecting cases for inquests or for a *post mortem* examination to local medical men who may be subsequently summoned as witnesses, and may claim fees for attending such inquests, or for making such *post mortem* examinations.

PAYMENT OF EXPENSES.—39. Some difficulties have arisen between coroners and medical witnesses, in reference to the payment of fees and expenses. The 6 and 7 Will. IV, c. 89, specifies in a schedule the amount of fees allowed by law to medical gentlemen summoned as witnesses; and under 1 Vict. c. 68, the coroner is directed to pay "all expenses reasonably incurred in and about the holding thereof, not exceeding the sums set forth in the said schedule". This throws a heavy charge on coroners, as they are only repaid quarterly. The pro-

visions of the Act are not observed. The local medical men, who should receive their fees immediately after each inquest, are left unpaid for weeks or months; and, in some instances, the coroner thus incurs a debt which is not always discharged without some trouble. The fees scheduled in the Act (one and two guineas) are not a sufficient remuneration for skilled analysts, when, in a suspected case of poisoning, a chemical analysis is absolutely necessary. A chemical analysis in cases of suspected poisoning takes a much wider range than that pointed out by the Medical Witnesses' Act. Since that Act was passed, the method of detecting absorbed poison in the liver and other soft organs has been discovered; and this is often of much greater importance in the trial of a case than the very limited analyses recited in the Act ("contents of the stomach and intestines"). It requires great skill, and the application of all the refinements of modern science in the hands of an experienced analyst. The analysis for absorbed poison should be made in all cases; if this be omitted, none may be found in the "contents" specified by the Act, and a guilty person may escape conviction.

40. The fees of skilled chemists for such analyses vary from five to ten, fifteen, and twenty guineas, according to the amount of research and the time occupied. A coroner cannot be expected to advance these fees out of his own pocket, with no certainty that they will be repaid to him at the quarterly meeting of magistrates. No analyst will undertake the chemical examination except under a guarantee from the coroner. I have known an instance in which the stomach of a man was hawked about the chemical laboratories of the London hospitals, but no professor would undertake the examination of it for the inquest, as the coroner could not allow more than the Parliamentary fee of two guineas! It was the case of a man dying suddenly in suspicious company, under a strong suspicion of poisoning. A long time afterwards, I heard that an inquest had been held, and a verdict returned of "Death from natural causes", in the absence of a proper analysis!

41. Coroners of large experience and long standing are sometimes allowed by the financial committee of county magistrates to give a guarantee to the analyst that the customary fees will be paid. Credit is taken for the heavy charges thus incurred at an inquest, and the amount is paid to the analyst at the quarterly settlement. In a large number of cases, the magistrates refuse to make any allowance beyond that of the schedule in the 6 and 7 William IV, c. 89. In the course of forty years, a number of stomachs, with suspected bottles of medicine, poisoned food, etc., have been brought to the laboratory of Guy's Hospital for analysis, but again taken away, because the usual fees for such analyses are not provided for by law, and the coroner naturally declined to pay them out of his own pocket. I believe that, as a rule, coroners are quite disposed to act honourably in the payment of scientific witnesses whose special services they require. In a very long experience, I can only recall two instances in which analyses were made by me for coroners and the fees were not paid. In these cases, no poison was found; but the suspicion of its existence gave rise to more trouble and research than if it had been present.

42. For many years, I have declined to make any analyses for coroners or magistrates, except under an order of the Secretary of State for the Home Department. In all cases of importance or of a mysterious or intricate character, the Home Secretary has not only granted the order so far as the inquest was concerned, but has ultimately paid also the fees for attendance at the subsequent trial, when the prisoner had been committed for trial.

43. These facts show clearly that coroners are placed in very great difficulty. The financial arrangements connected with them and their inquests require entire revision. They are expected to procure all the scientific evidence required to make these inquests perfect, and to enable the jury to arrive at a correct verdict, while the means for insuring this are denied to them.

44. If the Scotch procedure be contrasted with the English practice, it will be seen how miserably deficient our present system is. We are informed on good authority that, in Scotland, in all cases in which an analysis of the contents of the body is necessary, the Procurator-Fiscal must commit them to the Crown office in Edinburgh, there to be submitted to "skilled chemical examination". The analysts receive their proper fees, and the Procurator-Fiscal is not required to pay for them out of his own pocket.

45. There is no reason to believe that crime escapes detection more under the Scotch system of procedure than under the English; on the contrary, experience seems to show that, under the English practice, it is more likely to remain undetected. The crimes of William Palmer of Rugeley were brought to light by the mere accident of a pocket-book being missed by his stepfather, when called to see him lying dead. It was then found that he had previously poisoned, without detection, his brother and wife. Others of his family, including

friends to whom he owed turf-debts, had died under his roof under the suspicion of poisoning. The Rugeley undertaker informed me that, in two years, he had taken seven coffins into William Palmer's house. The case of Catherine Wilson furnishes another illustration. This woman was tried and convicted of the murder of a Mrs. Soames in 1862. The facts proved that deceased had died from the effects of colchicum secretly administered by the prisoner. Three other cases of poisoning by the same agent were then traced to her in the years 1854, 1859, and 1860. The case of Mary Ann Cotton, tried and convicted at the Durham assizes in 1873 of killing her stepson by arsenic, furnishes also a striking instance of the facility with which the act of poisoning may be perpetrated and concealed under the present system of conducting coroners' inquests. This woman, it was stated on good authority, had at different times killed by poison her mother, fifteen children, three husbands, and a lodger, making altogether twenty persons destroyed by arsenic in the course of a few years! They died rather rapidly one after another under similar symptoms. Inquests were held in some of the cases, and the cause of death was said to be gastric fever, thus proving that neither the medical man nor the coroner could recognise the symptoms of arsenical poisoning. I believe that such cases as these have never occurred, and could not occur, in Scotland under the Procurator-Fiscal's investigations.

46. Although the changes here advised for the English coroner's inquest would necessarily lead to great expense, I believe that, on a proper sifting of cases for inquests and *post mortem* examinations in England, there would be a reduction in the present charges which would cover any increase that might occur.

## THE ILLNESS AND DEATH OF KING VICTOR EMMANUEL.

OUR own correspondent writes from Rome under date January 14th :

The acute nature of the illness and the sudden death of the King have thrown a deep gloom over Rome. Nothing could be more impressive than the aspect of the population on Wednesday and Thursday last week. The general depression and the evident sense of personal loss exhibited by all prove that the unity of Italy is not a mere name.

The King had been ailing for about a fortnight previously to the onset of the pleurisy and pneumonia, on Saturday, the 5th instant. His symptoms were those of slight ague, feelings of cold, slight enlargement of the spleen, and perspirations. He had himself told the President of the Council of Ministers that he was well during the day and only ill at night, when he could not sleep. He had, however, driven out each day. During the night from Friday to Saturday, he had risen to smoke a cigar at an open window when in a state of perspiration and only lightly clothed. The next day (Saturday), at 1 P.M., he had a violent shivering fit, and was at the same time seized with acute pain in the right side of the chest. The same evening, at 11 P.M., he was seen by Professor Baccelli, sent by the Council of Ministers. He was then found to have very extensive pleurisy and pneumonia involving the whole of the right lung. The heart was dilated—both ventricles—and was probably fatty. Pulse quick, and very irregular. A very grave prognosis was given. The next morning, he was bled to a slight amount; but he never took the quinine, camphor, and anti-mony ordered to any extent, as throughout only one and a half *grammes* (about twenty-two grains) of quinine could be given. He tore off the counterirritants, too, that were used, and insisted on smoking cigars even when expectorating prune-juice coloured masses, and he continued to drink very large quantities of iced water. He took some sherry, but very little fluid nourishment. On Sunday, his symptoms were worse, and Baccelli gave a hopeless prognosis; but the bulletins were not worded as he wished, as the Council decided not at once to alarm the nation. With the same object, the official dinner that evening at the Quirinal to the diplomatic corps was not deferred. His state became aggravated on Monday and Tuesday, as described in the telegrams, and on Wednesday morning, at 5 A.M., he was sinking. Oxygen was then given by inhalation, and it had a great effect, as the cyanosis of the face, hands, and chest almost disappeared, and he was able to take the last sacrament and to say a few words. About noon, he turned over on to the left side, when his breathing at once ceased and he seemed *in articulo*. The physicians succeeded in raising him, however, and, by using the oxygen and by artificial respiration, he again rallied for a short time, but finally died in collapse at 2.30 P.M. The quantity of oxygen used on Wednesday was three hundred and twenty litres.

From the beginning, such an attack, in a man of Victor Emmanuel's

constitution, with the heart dilated and fatty, would obviously prove fatal; and Professor Baccelli even ventured to predict on Sunday that he would die on the fifth day. The body has been embalmed, but not very successfully, King Humbert having refused to allow the removal of the viscera. It seems certain that the wish of the nation is to be granted, and that the body of the most constitutional monarch any continental nation ever had is to remain in Rome.

### THE UNIVERSITY OF LONDON.

A MEETING of Convocation was held on Tuesday last, the Chairman, Dr. Storrar, presiding. The attendance of members was very large, and the greatest interest was evinced throughout in the proceedings. The chief business for discussion was the draft of a new supplemental Charter, ordaining that all the powers and provisions relating to the granting of degrees (excepting admission to Convocation, unless and until Convocation shall have passed a resolution for their admission), shall henceforward be read and construed as applying to women as well as to men. The Registrar announced that the regulations under which degrees in music are to be conferred had been approved by the Senate and the Home Secretary; and that the degrees in music would take the same high rank as those in the other faculties. The Chairman said that copies of the draft supplemental Charter had been circulated amongst the members, and that it might be taken as read. They were asked to concur with the Senate in surrendering the existing supplemental Charter, and in approving of the new proposals contained in the document which had been circulated amongst them. If they approved of it, the course which would naturally be taken would be to petition the Crown, on behalf of the University, to grant the new supplemental Charter to the University.

The report of the Annual Committee was then presented, and its reception moved by Mr. H. M. Bompas, seconded by Dr. Hilton Fagge. The motion was carried unanimously.

Mr. H. M. BOMPAS moved that the draft supplemental Charter be approved of. The real question, he remarked, which was raised by that document had been already considered by Convocation on two occasions, and each time that body had arrived at the same conclusion on the subject. For the sake of those women who were actually engaged in tuition, or who were looking forward to such work, it would be desirable that they should be permitted, if they chose, to go into the same examination with men and to be tested alongside of them. With regard to the question of actual practice, it seemed to him that the members of the profession should regulate the admission of others to such practice, and that the University should regulate the stamp of knowledge which should entitle them so to act. He was not sure that the admission of women to medical degrees would give them the right to practise; and he should be glad to see a scheme by which, in some way, their doing so would depend, not upon the University, degree, but upon a professional body of medical men. Several side issues had been raised during the last few weeks; but they must remember that in this case the Senate had adopted that plan which Convocation had said should be followed out.

Mr. T. HENSMAN seconded the motion. He said, Convocation should meet the Senate in the same spirit in which the Senate itself had acted in the matter. This subject had got beyond the point of argument. It had been more than once before Convocation; it had been fully debated; Convocation had confirmed the principle for which he contended; and he could not suppose that the latter body would now go back on its old lines, and so to a certain extent stultify itself with regard to its former votes.

Dr. W. TILBURY FOX said that those who constituted the medical section of the University were anxious to promote the acquisition of knowledge by women, and were not opposed to granting certain degrees to them, provided the subject were properly investigated. They had heard that the Chancellor of the University had issued a circular on this subject, but he thought the noble Earl (Granville) would have consulted his dignity much more if he had occupied a position of impartiality in the matter. But the circular had evidently been issued with the express purpose of influencing votes that evening. Lord Granville had said that he had written it in order to remove any misapprehension as to the feelings of the Senate towards Convocation; and in the course of the present debate it had been contended that the acceptance of the new Charter would be in accordance with the views

previously expressed by Convocation. The Chancellor said the same thing, but he maintained that the statement that the present proposal was one for which Convocation had always contended was not just to the members. They had confirmed the desirability of women being admitted to degrees, but not to the same degrees as men. They had not a single line placed before them showing the grounds upon which it was considered desirable to effect this radical change; and in the circumstances, would it be dignified on the part of the University to consent to it? He recommended unanimity, and asked why they should split up the University into sections at a time when a strong current of feeling was setting in against it. The opinion of the members of the Senate themselves on this question had only changed since last June, and the house ought to reject the proposed Charter on this account if on no other.

The CHAIRMAN here read a letter which he had received from Earl Granville, enclosing a copy of a letter addressed to Dr. W. T. Fox, in answer to a letter giving his reasons for thinking that a statement in his (Earl Granville's) letter to the Chairman was not in accordance with the facts. The copy of the letter was forwarded to meet the charge, if it should be made at the meeting. Earl Granville referred to the resolutions passed on this subject by Convocation from 1874 in proof of his statement, that the supplemental charter was in accordance with the previously expressed views of that body; and, with regard to the statement that the article "the" in the words "the degrees" in a resolution had been inserted by mistake, his lordship said the resolution, as communicated to the Senate, contained the word "the", and it must be interpreted according to its terms. The letter concluded as follows:—"In these circumstances, I consider my statement as to Convocation having on three different occasions recorded its opinion in favour of admitting women to degrees in all the faculties is not fairly open to the remark that it is not consistent with the facts."

Mr. T. S. OSLER, LL.B., a member of the Senate, having spoken in reply to some remarks of Dr. Fox,

Mr. T. TYLER spoke against the Charter, and Mr. J. G. FITCH and Mr. CREAK in its favour.

Dr. QUAIN held that no proposal could be more injurious to the University than that which was contained in the proposed new Charter. It could not fail, if adopted, to hurt the institution as a whole; while to the Medical Faculty in particular it would be simply ruinous. Dr. Quain next read some correspondence showing that women did not want the degrees of the University, and that, if they had to compete for them, they must give up the study of subjects which were likely to be of the utmost advantage to them in their various vocations in life. He thought the Senate and that House should seek to establish a separate University for women, or perhaps a separate department in the University of London for women. Those for whom he spoke were not opposed to the admission of women to certain departments in connection with the medical profession; but they must be kept in their proper places; for nothing could be more unfit for them than the practice of that profession to its full extent.

Mr. BLACKWOOD opposed the new Charter, on the ground that it would be injurious to women themselves.

Sir WILLIAM JENNER said reference had been made, in the course of the discussion, to the letter which had been issued by their chancellor. As to whether it was a dignified proceeding for Lord Granville to issue that letter, he should not say. They had all their opinions on the subject; but he thought that their chancellor, having descended from his high position to send out what he must term an electioneering circular, should never have said that the Senate had entered into a compromise. Where had the compromise been shown? He maintained that the chancellor was not justified in stating that there had been any compromise at all on the part of the Senate. With regard to the general question, he did not yield to any man in his desire that the education of women should be improved; but he denied that that effect would be produced by giving them degrees in medicine, and by obliging them to undertake the course of study through which they would have to pass. He had one dear daughter, and he would rather follow her to her grave than allow her to go through such a course of study. He held up both his hands, and he earnestly prayed that those who knew but little on this subject might follow those who ought to know a great deal about it.

Professor LISTER thought it would be a serious thing for Convocation to force upon the Medical Faculty a measure which he was firmly convinced the majority of the graduates in the profession to which he belonged viewed with detestation. If anything were to be done in the matter of degrees at all, let it be done after the most careful consideration as to what honours should be opened up.

Mr. HERSCHEL, M.P., pointed out that the proposed new Charter was not compulsory, but merely gave certain powers which it would

be open hereafter to the governing body of the University, influenced, if they would, by the views of Convocation, to put into force, in whole or in part, or, if they were of such an opinion, not put into force at all. As regarded the Senate, he believed that in this matter it had bowed to the will of Convocation, and he hoped that no gentleman present would vote against the proposal simply because of any feeling of resentment against the Chancellor for the letter which he had issued.

After a few words from Dr. MURRAY and Mr. ADAMS in support of the supplemental Charter,

Mr. W. H. HARKFORD said he would regard it as a distinction if a daughter of his were able to fit herself for taking a part in the world which would enable her to help her fellow-creatures with the skill of her male colleagues, and, at the same time, with that delicacy and tenderness which but too seldom belonged to men.

Dr. WILSON FOX would vote against the proposed Charter, because it would admit women to medical degrees.

Dr. PYE-SMITH said that, in connection with the Senate, Convocation had achieved a great victory, and it was their true policy to register that victory on the present occasion. It would be an advantage to the University to get questions of dispute out of the way, so that subjects of reform could be discussed. As Liberals in the best sense of the word, they could not deny the claim of women to try for degrees. With regard to what had been said of the subjects of medical study, they knew that the familiarity of scientific study took off the effect of what, without the study, would be obscene. What would otherwise be impure, was sanctified by the desire for knowledge, and the wish to alleviate human suffering. What already applied to medical students, to nurses, and to sisters of mercy, would apply to women generally. The question which had been urged upon them was one of difficulty, and the best course was to act boldly. Let the experiment be made. He should vote for the Charter in the interests of peace and reform.

Dr. MOXON said that Mr. Herschell had seemed to say that, because Convocation had three times voted for this question, therefore Convocation for all time should be bound thereby. This could not be, any more than that the Senate were to be bound by their former votes, which were opposed to the admission of women to degrees. If one accepted the equality of women in intellectual acquirements, then logically some day they must be admitted to Convocation.

Dr. BUCKNILL would vote against the Charter, on the principle that what was called the higher education of women was mischievous. All who had studied physiology and psychology were of that opinion.

Mr. BOMPAS, in reply, said that, if the medical graduates voted against the Charter, they would take away from the Arts and Science graduates the power to admit women to degrees; whereas, if the Arts and Science members of Convocation, in voting for the Charter, passed it, the carrying out of its proposals as far as regarded the medical degrees must rest with the medical members of the Senate.

A show of hands was then taken, and declared to be in the affirmative. Upon division, the numbers were: Ayes, 242; Noes, 132; the majority for the Charter was consequently 110.

## MEDICO-LEGAL CASES.

### A RAILWAY CASE.

IN the case of *Durrant v. the Midland Railway Company*, to which we have already referred, a rule *nisi* was moved for a new trial this week, on the ground that the verdict was against the evidence as to the total loss of eyesight, and also the damages were excessive in amount. After hearing the arguments, the Lord Chief Justice said the case had assumed a very painful character; for the counsel for the railway company did not hesitate, in the face of the verdict of a jury for such heavy damages, to impute downright imposture to the plaintiff. But there was nothing in the evidence to warrant the imputation; for even the medical witnesses for the company did not deny a very serious injury, and the court would hesitate long before they set aside a verdict upon such an imputation, which appeared to be without foundation. Whether or not the damages given were more than adequate, it was difficult to say, because it might depend partly on the possible loss of eyesight. On the one hand, if loss of eyesight ensued, the amount of the verdict would be hardly adequate; and, on the other hand, even setting that aside, it could hardly be said that the amount was excessive. The verdict therefore ought, in his opinion, to stand. Mr. Justice Manisty concurred, and accordingly the verdict stands.

## ASSOCIATION INTELLIGENCE.

### BATH AND BRISTOL BRANCH.

THE third ordinary meeting of the Branch will be held at the York House, Bath, on Wednesday evening, January 30th, at a quarter past Seven o'clock: H. MARSHALL, M.D., President.

The evening will be devoted to the discussion of Hospitalism, which will be opened by R. W. Tibbits, M.B.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, December 31st, 1877.

### DUBLIN BRANCH.

THE first annual meeting of this Branch will be held in the Hall of the King and Queen's College of Physicians, Kildare Street, on Wednesday, January 30th, at 4 P.M. The President, Dr. HUDSON, will deliver an address.

The annual dinner of the Branch will also take place at 7 P.M. the same evening in the College.

GEORGE F. DUFFEY, M.D., *Honorary Secretary.*

30, Fitzwilliam Place, Dublin, January 8th, 1878.

### THAMES VALLEY BRANCH: ORDINARY MEETING.

AN ordinary meeting of this Branch was held at the Spread Eagle Hotel, Wandsworth, on December 18th; Dr. PRICE JONES in the chair.

*Communications.*—1. Dr. HOOVER related a case of Intussusception in a Child.

2. Dr. BATEMAN read a paper on Muco-Enteritis.

3. Mr. BATEMAN showed a case of Amputation at the Ankle-Joint by Pirogoff's operation.

*New Member.*—Mr. Franklin was admitted a member of the Branch.

*Dinner.*—The members afterwards dined together.

## SPECIAL CORRESPONDENCE.

### PARIS.

[FROM OUR OWN CORRESPONDENT.]

*M. Raspail.*—*Magic Pipe.*—*Infectious Diseases in General Hospitals.*—*Ethnographic Gallery.*—*Prevention of Fires.*—*Sir Richard Wallace.*

THE name of M. Raspail, whose death has been announced in the JOURNAL of last week, has been so intimately connected with the profession that a short biographical sketch of his life may perhaps not be unacceptable. François Vincent Raspail was born at Carpentras, on January 29th, 1794, of poor parents. His father, though a simple publican, had him educated for the Church; but, finding himself unsuited for such a calling, young Raspail turned his thoughts in another direction, and soon became Professor of Natural Philosophy and Theology at Avignon, in which capacity he distinguished himself, so much that, in 1812, being then only eighteen, he was brought to the notice of the Emperor Napoleon, who, with his keen-sightedness, saw in the young professor something out of the ordinary. This prognostication, as has been seen during his subsequent career, was fully realised. In 1816, he came over to Paris with the view of improving his position, but had to work hard to earn a livelihood. During the day, he gave lessons on literature, and during the night he worked at chemistry and botany; and, among his earliest productions as an author, may be named his work on Organic Chemistry, a Memoir on Vegetable Embryos, and another on the Organisation of Flowers. He was of an irascible disposition, and quarrelled with everybody who differed from him. He entered into warm controversies even with the princes of science, and he looked upon Cuvier as his great rival in natural history. The senior members of the profession may well remember the part he took in the celebrated case of Madame Lafarge, on which occasion he was appointed by the Court to control the analysis of the great chemist Orfila, the expert for the prosecution, whom he actually accused of having surreptitiously introduced the arsenic (the substance alleged to have been used for the accomplishment of the murder) into the matter which M. Orfila was analysing. Without having studied even the principles of medicine, he created a system of therapeutics of his own, based on the theory that all diseases were of parasitic origin, and that camphor was

the antidote. This substance was accordingly prescribed by him in every variety of form, both internally and externally, and camphor cigarettes became the fashion; and, in order to give his theories a serious character, he published a work entitled *Manuel de la Santé*, which is a sort of household guide, and is to be found in almost every family throughout the country. This haphazard sort of practice soon brought him an immense fortune, which naturally excited the jealousy of the regular practitioners, who sued him for illegal practice, for which he was fined a nominal sum. Not content with the reputation and fortune he thus created for himself, he rushed into politics; but here he was not so successful as he was with his camphor, for he more than once got into trouble, and spent a great part of his life in prison. Who among those who have visited Paris does not remember the dramatic tomb, erected over his wife at the Père la Chaise, representing the wall of a prison, through the bars of the window of which the hand of Raspail is passed as if in expectation of meeting that of his departed wife? M. Raspail was also a member of the Chamber of Deputies, and was as great a fanatic in politics as he was in everything else. He had a large property at Arcueil, not far from Paris, where he died on Monday, the 7th instant, from an attack of pneumonia. He leaves four sons: Benjamin Raspail, who was a painter by profession, but which he has given up for politics; Camille is an "Officier de Santé", and keeps up his father's practice; Emile, the third son, is a chemist, and superintends the fabrication of the products employed in the therapeutics instituted by his father; and lastly, Xavier Raspail, who is a physician, but he also has sacrificed his profession for politics. The remains of the great democrat were interred at the Père la Chaise, in the midst of an immense crowd, representing all classes of society, both official and otherwise; and, being a member of the Chamber of Deputies, he received the honours due to his rank.

In my letter of November 17th, I brought to notice the hygrometric flower that has been much in vogue in Paris. The novelty in Paris now is a "magic pipe". This resembles an ordinary clay-pipe as long as it is confined to its case, but, as soon as it is exposed to the air, or rather to the light, it becomes intensely brown, very much resembling the colour eagerly sought after by professional smokers. Others, again, are so marked as to form different designs, such as caligraphic characters, words, distichs, proverbs, and even portraits. The invention is due to MM. Dagron and Gislou, who have published the composition of the liquid employed. It consists of ether and alcohol, to which is added a little essence of rose or other essence, in which is dissolved about 10 per cent. in weight of camphor and 10 per cent. of borax. To this is added a slight trace of a salt of silver, such as the nitrate, to obtain a coating easily impressionable to light and easily fusible by the heat in the pipe, which is dipped in the solution with the designs previously traced on it.

The question, often discussed, about the isolation of patients suffering from infectious diseases, is at last about to receive some attention through the persistent efforts of the medical members of the Municipal Council of Paris, and the reiterated representations of the medical staffs of the different hospitals, particularly those of the children's hospitals, where the mortality is in excess, owing to the monstrous practice of conglomerating all the patients together irrespectively of the nature of their maladies. Thus it has frequently happened that a child, admitted with a mild affection and perfectly curable under ordinary circumstances, contracts an infectious disease, such as croup or diphtheria, from which it almost certainly dies.

A new Ethnographic Gallery has just been opened at the Hôtel des Invalides. Here may be seen a number (about seventy) of the different types of the warriors of America, Asia, the coasts of Africa, and of the different ocean isles, of the natural size, made of plaster of Paris, and painted with great ability. The statues are represented with the arms, costumes, ornaments, and the different articles worn by the men, sufficiently indicating the manners, habits, and the mode of fighting of these different people. Such a display is, we believe, not to be seen anywhere else; and is due to the initiative of Colonel Le Clerc, the indefatigable Director of the Ethnographic Section of the Museum of Artillery, who hopes soon to add to the above a suite of Greek, Roman, and Gallic warriors, which will form the natural introduction of a gallery for French and foreign modern combatants.

I lately brought to notice an extensive fire which took place at the Hôpital Saint Antoine, on which occasion the wooden huts annexed to the building were burnt down and some lives lost. This naturally led to serious inquiry on the part of the authorities; and Dr. Loiseau, a member of the Municipal Council of Paris, suggested that such disastrous consequences may be prevented by previously injecting into the wood with which huts are made a solution of alum, and painting it over with the same substance, mixed up with any other paint desired. This may be useful even for household furniture.

In acknowledgment of the services munificently rendered to the Parisians from time to time by Sir Richard Wallace, and particularly of the drinking fountains liberally established by him all over Paris, it is proposed to erect, in some public place in this town, a gigantic fountain, surmounted by the bust of the illustrious philanthropist, as a lasting tribute of a grateful people.

## CORRESPONDENCE.

### THE LOST MEDICAL SCHOOL.

SIR,—Without further inquiry, we may now take it for granted that there is at present no Medical Faculty at Oxford; that there is in that city a large and amply sufficient Infirmary; and that there are in the possession of the Colleges and University funds sufficient to pay a staff of first-rate men as professors. What the Commission should, I think, be asked to do is to assign funds for the payment of such a staff; namely, an uniform sum of £1,000 a year to each ordinary professor (the sum already determined on by Trinity College, Cambridge), and £300 a year to each extra-professor. The staff, once appointed, should have power to draw up a medical curriculum, commencing with a matriculation examination and ending with the M.B. degree. The time occupied by this curriculum should not exceed five years, and the whole course should be fully carried out from beginning to end within the precincts of the University. Students, though perhaps they might be permitted for special reasons to do so, should not be encouraged to take any part of this five years' curriculum elsewhere than at Oxford. The Oxford degree should be for Oxford men, and should mean that its holder has received such a thorough academic training in the medical arts and sciences as no medical school appended to a London hospital (the endowments of which cannot be employed in its support) can ever be expected to give.

The staff which the Commissioners have to create for the restored Medical Faculty of Oxford, to be paid at the rate above mentioned, must be, at the very fewest, as follows.

1. Professor of Medicine (allowed to practise).
2. Professor of Surgery (allowed to practise).
3. Extra-professor of Gynæcology (allowed to practise).
4. Professor of the Surgical and Regional Anatomy of the Human Body (with dissecting-room and endowed demonstrator).
5. Professor of Physiology (with laboratories and endowed demonstrator).
6. Extra-professor of Physiological Chemistry (possibly this should be a full professorship).
7. Professor of Pathological Anatomy (with laboratory and endowment for assistants and demonstrator).
8. Professor of Therapeutics and Materia Medica (with laboratories and endowment for assistants).
9. Professor of Hygiene and State Medicine (with laboratories and workshop).
10. Extra-professor of Medical Jurisprudence.
- 11, 12. Extra-professors of Medicine and Surgery, to take part in clinical and elementary instruction.

The precise duties of the offices thus created should be laid down, and power given to the Medical Faculty as a body (in which certain of the professors of the branches of physical science would be included: viz., those of chemistry, botany, and zoology) to coerce its members, so as to ensure the due delivery of the lectures and practical teaching demanded by the curriculum.

Were these arrangements made, and were the student intending to study medicine freed from all "schoolboy studies" on passing an entrance or matriculation examination (which, in a few years' time, not even the most infatuated pedant will expect to comprise the rudiments of Greek), we should have, in a very short time, a school of medicine and physical science in Oxford, which, though probably less numerous than that of Edinburgh, would be the largest and best equipped

in England, and the most efficiently arranged in the kingdom, for the profound study of the scientific bases of medical practice.—Yours faithfully,  
A MEMBER OF CONVOCATION.

SIR,—The following further particulars relating to the history of the abused medical endowment at Oxford will serve to complete the partial information afforded by the letter of "A Member of Convocation", and will, I hope, do some service in helping you to press forward the much needed reform for which that letter establishes the grounds, and in promoting which I trust we may count upon your powerful aid.

The Regius Professorship of Medicine (now held by the same person who holds the Clinical Professorship) was assigned a stipend of £40 a year by Henry VIII. James I added to it the "Mastership of Eveline Hospital". In 1624, Mr. Richard Tomlins of Westminster annexed to it a Lectureship in Anatomy (of course, Human Anatomy in relation to Medicine); and, in 1803, by the will of Dr. George Aldrich, a Professorship of Human Anatomy was superadded to these. Dr. George Aldrich also endowed a Professorship of the Practice of Medicine; so that, at the beginning of the present century, there were in Oxford three Professors of Medicine; viz., the Regius, the Aldrichian, and Lord Litchfield's Clinical Professor. Each of these offices was distinct; the ingenious device of giving them all to one person to do nothing did not at first occur to those concerned. The Regius Professor was at this time, and is now, distinctly bound by statute to give one course of lectures in the year "on Celsus, Galen, or Aretæus, or on the Practice of Medicine". In the first quarter of this century, he had further the duty of teaching human anatomy, as provided for by the Tomlinsonian and Aldrichian endowments. In addition to the three professorships already mentioned, the trustful simplicity of her medical sons has resulted in yet another endowment for the promotion of medical study in the University of Oxford: an endowment which, like all the others, has been shamefully misappropriated, though no blame can be attached in any sense whatever to the present recipient of the benefaction in question. Dr. Lee, at the end of the last century, made the Dean and Chapter of Christ Church the trustees of his property, which was to be employed in paying a reader in chemistry and a reader in anatomy, the latter post being founded for the express purpose of promoting the study of human anatomy as relating to medicine. This endowment has now been diverted by the ecclesiastical corporation to which Dr. Lee foolishly entrusted it. The clergy have proved themselves the deadly enemies of the Medical Faculty at Oxford, and Dr. Lee's Readership in Anatomy (worth £300 a year) is now misapplied in paying a gentleman to coach the undergraduates of Christ Church in zoology for their B.A. degree.

One reason of the failure of the Medical Faculty and the collapse of the various medical offices from time to time founded, is the smallness of the stipends assigned by the endowments. Dr. Acland receives, as Regius Professor, Master of Eveline, Aldrichian Professor, Clinical Professor, and Chief Examiner in the Medical Faculty, something less than £800 a year. In addition, however, he is Radcliffe's librarian: a post to which Dr. John Radcliffe assigned in 1714 a salary of £150 a year. Since Dr. Acland has held this post, the library of works on medicine and physical science, brought together in pursuance of Radcliffe's directions, has been removed from its beautiful receptacle, the well known dome, and the trust altered by making the Radcliffe funds supplement the Bodleian Library. The two libraries are now mixed up to a large extent, and the Bodleian librarian refuses to buy works on physical science.

You, sir, have rendered many and great services to the medical profession at large, and there can be none in which you can use to better effect the just influence which you have acquired in the profession than in moving the profession by organised proceedings to restore to medical science and medical education their part in the powerful and great education resources of the University of Oxford; nor, indeed, can any of the sons of the University who think with shame of the past

neglect and injury inflicted upon medicine and upon the University by the misappropriation of the endowments intended for the purpose of promoting medical education, engage in a task more grateful to the best wishes of the University, or more fitly atoning for its shortcomings and its faults than in assisting the present movement to swell the voices of those who have found in your columns a hopeful means of making their voices heard, and who may count, I hope, upon the aid of the British Medical Association to see that the question so raised shall not carelessly be let fall upon the ground and buried once more in the dust.—I am, etc.,  
A LIBERAL CONSERVATIVE.

SIR,—I have only to-day seen the letter of "A Member of Convocation", and I lose no time in writing to your JOURNAL. I would, however, at once say that I do not in any sense intend to answer "A Member of Convocation", or to enter into a discussion with him. My object is twofold: to assure your readers who are not Oxford men that he does not represent the general feeling, nor (Heaven save the mark!) the average of good feeling of my university; and, secondly, to assure my old teacher and friend how affectionately and gratefully he is borne in mind by the large majority, I am quite sure, of his pupils. I think it is high time that this should be done; for we have for some time been annoyed either, it may be, by several jealous and discontented men, or, it may be, by one such person under various aliases; at any rate, by a series of personal attacks sent anonymously to a series of journals, showing more or less spiteful ingenuity, directed against Professor Rolleston. From behind the breastwork of a pseudonym, the enemy wages from time to time his chivalrous warfare with a feeling of security.

I protest against the right of "A Member of Convocation" to stand godfather for the body of science students, past and present. Professor Rolleston, as a scientific man, has no need of any apology or defence from any man; but, when he is attacked as a teacher, his pupils must be his champions.

Let me assure your readers and him that few indeed of those whom he has taught fail to remember with gratitude the devotion with which he has always laid himself at their service, and that not a few feel that, while his teaching has been most valuable to them, the example of his remarkable energy, his ardent enthusiasm, and his hatred of what is petty and mean, have been appreciable motive forces which have sensibly helped them again and again in the struggle for existence. I would add that the number of his students has increased instead of diminishing. "prehistoric pigs" or not.

The question of how far Oxford would be the better or the worse for being a regular medical school is a large one. You have seen one side; the other side is that, in a limited space of time, it may surely be better to confine studies to the purer scientific branches. I believe, and so do many others, that we are all the better for studying human anatomy and physiology at Oxford only so far as they are parts of the larger department of comparative anatomy and physiology. At any rate, a tree is known by its fruits, and I do not see among the men who come up from Oxford to the London hospitals that flippancy and want of preparation which ought to result from the lamentable arrangements over which "A Member of Convocation" weeps crocodiles' tears. On the contrary, Oxford can there hold her own, to say the very least.

There are "Members of Convocation" who are not a little indebted to the professor whom your correspondent abuses. He, no doubt, owes nothing. Reforms may be needed at Oxford from time to time, but proposed and carried out in a very different spirit from his. I have always been, and still am, proud of my university, and of the work which she is doing. I can only see one prospect of my ever feeling ashamed of her; but I should, indeed, be heartily ashamed of my connection with her if ever the day came for her to be represented by men showing no more good feeling than "A Member of Convocation".—I am, sir, your obedient servant,

FRANCIS HENRY CHAMPNEYS, M.B. Oxon., M.R.C.P.;  
Casualty-Physician to St. Bartholomew's Hospital;  
Formerly Radcliffe Fellow.

11, Wyndham Place, Bryanston Square, Jan. 12th, 1878.

SIR,—I have read with great interest the correspondence upon the Oxford School of Medicine, and, as one who has had some practical acquaintance with it, I should be glad to make a few remarks as the result of my experience. These I would preface by an expression of astonishment that "A Member of Convocation", who has ventured to make most serious charges against two of his colleagues, should have lacked the courage to sign his name. I, who must follow his example

in writing anonymously, shall avoid, as far as possible, the personal matters raised by his letter. Both the objects of his accusations are doubtless well able to defend themselves, if they think it desirable. As one who recognises the debt that science in Oxford owes Professor Acland, I would respectfully urge him to abandon for once the good rule of refusing to notice anonymous accusations, and, in view of their gravity in the present instance, and out of regard to the university which he represents, to state to the public his conception of the duties of his offices, and the manner in which he fulfils them. As a former pupil of Professor Rolleston, I would add my testimony to that of "Two Oxford Graduates in Medicine" to the unflinching zeal, energy, and patience with which he not only introduces beginners to the first principles of biological science, but also advances that science step by step each day he works by the unwearied researches of his "leisure" hours.

In common with many others, I attribute the small number of medical degrees conferred at Oxford in no slight measure to the difficulties thrown in the way of candidates by the faulty arrangement of the examinations, and, with your permission, I would sketch the university career of the ordinary type of man, one not clever, not proficient in natural science or any other branch of learning, but one of those men of average attainments, such as two-thirds of the undergraduates possess, whose wants the university, to be worthy of the name, is bound to supply.

Under the present system, such a man, after passing moderations at the end of his first year, has to pass the Preliminary Honour examinations in Chemistry and Physics before he can present himself for examination in his Honour subject, which will probably be biology. In this, we will suppose he gains a first-class at the end of his fourth year, and then goes to London and begins the first year of his recognised professional education with a good knowledge of physiology and histology, a vague notion of ordinary descriptive anatomy, and a hazy recollection of his Preliminary Honour subjects passed probably two years ago. Strangely enough, these last subjects he has to resuscitate for his "first M.B. examination"; and, while all his energies should be concentrated upon human dissection, he has to devote much of them to renewing his acquaintance with such topics as the mechanism of the steam-engine and the laws of falling bodies. This "first M.B." is not only extraordinary in the number of its subjects, but also in the high standard of knowledge expected in them (botany excepted), especially in physiology. Reference to last December's papers will show this, and further, that many more questions are set in subjects of secondary than in those of primary importance in medical education. Thus, on the last occasion, about twenty-four questions were asked in physics and mechanics to four or five in human anatomy. As might be expected, the result of such an examination is sometimes not a little peculiar. Not so very long ago, a candidate who had recently passed the primary examination for the Fellowship of the R.C.S.E. failed at the same time that another who had not then dissected an entire body passed. I would bring to your notice that failure entails a year's delay.

And, if it be difficult for a man who has studied science at the university to master this multiplicity of subjects, success is almost impossible for one who only begins to work for the examination when he has entered on his hospital life in London. The Cambridge method ensures a fairer test and works better. There the subjects comprised in the one examination at Oxford are distributed amongst two, and the addition of *Materia Medica* to the second examination does not prevent this arrangement from much facilitating the preparation of the work.

I cannot ask you, sir, to give me more space than that sufficient to briefly suggest a few alterations, which would, I believe, be improvements upon the present system.

1. At least let men be excused from taking up for their "first M.B." the two subjects in which they have passed in the Preliminary Honour School.

2. Abandon the idea of making Oxford a seat of instruction in medicine and surgery, subjects surely better studied in London than in the best provincial school; establish instead a final Honour examination in human anatomy and physiology alone, to be taught practically by demonstrators, as in our London hospital schools. Were such a plan as this carried out, the Colleges of Surgeons and Physicians would, I imagine, allow a man to register directly he had passed moderations, and the student would combine all the advantages of an university life with the prosecution of his professional studies. By this method, the present "first M.B." would be divided into two examinations: the first part comprised in the Preliminary Honour, while the Final Honour examination would embrace the other remaining subjects. The last two years of professional education might

most advantageously be spent in London, and the degree of M.B. would be attainable in the more reasonable time of five years or a little longer, instead of as at present from seven upwards.—I am, sir, your obedient servant,  
AN OXONIAN.  
January 15th, 1878.

#### PHYSICIANS' FEES.

SIR,—Some time ago, I addressed you on the subject of consultants' fees, and I complained of the practice of the leaders of the profession, who charge fees which to the public and to the profession seem ludicrously inadequate. If I wish a patient of my own to see one of the leaders of the profession, I always ask for a special appointment, stating that the fee will be from three to ten guineas, according to the means of the patient and the importance of his case. Otherwise, I receive a courteous letter from the consultant, and an opinion worth less than my own—worth less because the case has been but half investigated. We seek the advice of our leaders in cases of difficulty; and it is absurd that, when I and others have made a minute examination of a case, using all known methods, physical and chemical, we should be put off with a clever gloss arrived at in twenty minutes and written out in three. We require a careful written opinion, going fully into every point, as counsel in such cases would do, and paid for at a like rate. What would the Solicitor General or Sir Edmund Beckett charge for a careful opinion on a difficult point of law? It is absurd that the heads of our profession should lose time and lose money in a sort of gossiping out-patient practice which pays them little more than one guinea per consultation. Many fashionable physicians are really thus forgetting what "going into a case" means. Let physicians in London, at any rate, give up promiscuous morning receptions, as they find they can venture upon it, and see patients only by appointment and at fees proportioned to the time required, say, at an average rate of five guineas per consultation. They would make more money at less wear and tear, and with far more intellectual advantage to themselves and to the profession and the public.

Turning now to the other points under discussion, and speaking anonymously myself as a medical consultant in very large practice, I may say that the loss of fees, so much complained of, is to me unknown or scarcely known, and I cannot understand how it happens to be known so well to others. Occasionally, the shillings are filched from one's fees, but this is not common; and when I know those who do it, I add a guinea to my usual charge, and am careful not to remit fees to them on small occasions. I keep no books, and the few people who leave my chambers without payment have invariably forwarded a cheque when informed of the fees due. This information is sent, not by bill but by a written note on my behalf. I think those consultants who lose money must be more or less family practitioners, undertaking, that is, attendance upon patients at their own homes. This is clearly out of the province of a consultant, and if he be not paid for his services he must not complain. As a country consultant, my fee is one guinea for every visit of importance, but I am glad to encourage the return of a patient who merely calls to report progress. I always charge two guineas for single consultations, upon which much may turn, and for all consultations at which the family attendant is present. "General Practitioner" is surprised at this: I will explain my reasons, at any rate. Such consultations are, as a rule, serious ones and in important cases. They mean, first, a talk with the medical man alone; then with him and the patient; thirdly, again, with the medical man alone; and finally, with both him and his patient together. I beg to add, that any consultant who takes for granted the medical man's report of physical conditions, etc., does not earn his fees or do his duty to the patient. Moreover, medical men cannot wait a consultant's convenience, and thus some further trouble is caused. Another general practitioner points out the folly of his brethren in shirking consultations. No men are more anxious than these very men for consultations when themselves in illness, nor can I imagine anything more unsympathetic than to deny or fail to secure to sick people a full discussion of their own case. No intelligent person will choose to deprive himself of such advantages. The result is, that they come unknown to their own attendant, and forbid the consultant to write to him because "Mr. So-and-so is so touchy" on this subject. I fear consultants are somewhat to blame in this, as they have not been in all cases so careful as they should be of the reputation and skill of the general practitioner. The consultant feels he is coldly regarded, and if he be not very scrupulous may take a little quiet revenge.—I am, sir, yours, etc.,  
A COUNTRY CONSULTANT.

January 14th, 1878.

P.S.—A practice has sprung up in London of charging one guinea for consultation and the second guinea for writing to the private

attendant. This is most objectionable, as patients are, as it is, far from ready enough to allow letters to be written to their own attendants, and prefer to "take a prescription"—a proceeding really far less for their interests and for our own.

SIR,—As you open your columns to a discussion on the subject of fees, I beg your permission to point out that much of the difficulty which consultants feel in raising their charges above the time-honoured guinea must really be placed at the doors of those who are at the top of the tree, and who fail to set an example which would enable other and less employed men to follow in their footsteps. When such men as Jenner, Paget, and Gull, and a few more that could be named, do not ask more than a guinea for a visit or two guineas for a consultation, you cannot be surprised that things should stop as they are. Is it not really an absurdity that such men should drive out, say to Notting Hill, give half or three-quarters of an hour's consultation, and, when asked their fee, claim two guineas? I am satisfied that many patients would think more of their opinion, and quite as readily pay their fee, if they asked five guineas for a single consultation; and that would be much more like the sum which a barrister of equivalent standing would charge for the same amount of work. Many consultants ask two guineas for a first visit; but I doubt if those I have named do so. What I would suggest is, that some half-dozen of the leading physicians and surgeons—men who can command work, whatever their scale of charge may be—should agree together to make some change in the direction indicated. Were this done, others could follow in their wake; and this would have a beneficial influence through all ranks of the profession. But, until some common action is taken, and until the example is shown by some of our leading men, who really owe a duty to their less fortunate brethren, it is to be feared that it will be long before any satisfactory result is arrived at.—I am, etc.,  
F.R.C.P.

January 12th, 1878.

SIR,—As a physician in busy practice in one of the largest provincial towns, in which there exists a flourishing medical school, I have long felt that the question of physicians' fees, and the relations of physicians to their professional brethren and to the general public, was one which ought prominently to be brought forward in the medical journals and at medical societies. I rejoice that the subject has at last been taken up in the columns of the JOURNAL. I wholly agree with "General Practitioner" in his opinion that what is required is "a thorough and proper understanding between the consultant, the general practitioner, and the public"; if such existed, physicians would have little doubt as to the amount of their fees, and little trouble in securing them. Whether general practitioners are pleased that it should be so or not, there will always be a large body of consultants whom the public will recognise, and to whom they will appeal in cases of unusual danger or difficulty: a body made up of eminent physicians, eminent surgeons, and eminent specialists.

Much, if not all, of the confusion which exists as to physicians' fees arises from a confused notion in the public and professional mind as to what a consultant is. Let this idea be clear, and there will be no difficulty as to fees. For this confusion both consultants and general practitioners must be held responsible. Those consultants have mainly contributed to it who have habitually practised as general practitioners; but general practitioners have been accessory to this anomaly, and have borne their share in the result, by wrongly continuing to recognise as consultants men who are so styled falsely, and who are general practitioners, like themselves, differing only from them in holding hospital appointments, in occasionally being consulted, and in gaining a remuneration for their work as general practitioners usually a little higher than that which their brethren can secure. It is expedient and right that general practitioners should meet each other in consultation. I would encourage such conferences. But there must be no mistake; one general practitioner has no right to expect another general practitioner to meet him in consultation as a consultant, and to acknowledge him as such in fees and in precedence, whilst outside the particular case in which they are engaged they are competitors in general practice. It is often asserted, and sometimes, I am afraid, with truth, that general practitioners are averse to consultations. If this be true, in the interests of the public, such aversion is to be regretted. But that many general practitioners favour rather than resist consultations, every physician knows. Such an aversion, however, may not unreasonably arise when general practitioners know that their own particular sphere of practice is trespassed upon largely and systematically by many so-called consultants. To a very great extent, general practitioners have the remedy for these abuses in their own hands; let them always use their influence in favour of consultations, whenever the need

for them fairly arises; but let them take care that they use that influence, so far as they may do so with due regard to the interests of the patient, towards securing as the consultant some one who is really worthy of the name.

In medicine, what ought a consultant to be, and what ought he to do? He ought to be a man of high academic standing and of wide and liberal culture; he ought to hold, or to have held, some distinguished public appointment as a physician, which secures for him a large and varied experience in the management of disease; he ought to have done, or be engaged in doing, some work for the advancement of his profession. He ought not to practise as a general practitioner; that is, except in his own consulting-rooms, he ought only to see patients in conjunction with their ordinary medical attendant; and he ought always to receive his fees at the time when the service by which he earns them is rendered. Such a standard of character and conduct would shut off many from consulting practice who are now getting some of it, or who are now expecting some of it. Such a man as I have described must be content to work hard without pay, and to wait long for remunerative employment, while perhaps he sees many who were his fellow-students earning in general practice a comfortable competence; but the time will surely come, sooner or later, if he have worked well and wisely, and if he have kept an unspotted reputation, when he shall reap an abundant reward in the justly won confidence and support of his profession and of the public.—I am, etc.,

January 14th, 1878.

A PROVINCIAL PHYSICIAN.

### THE ACTION OF CHLORAL.

SIR,—I am requested by the Chloral Committee of the Clinical Society of London to beg the favour of the insertion of the accompanying letter and queries; and to express a hope that those members of the profession with whom we have been unable to communicate individually may also aid our inquiry by contributing the results of their experience. Copies of the circular may be obtained on application to the undersigned, at the Clinical Society's Rooms in Berners Street.—I am, sir, your obedient servant,

ROBERT FARQUHARSON, Honorary Secretary.

Brook Street, January 1878.

"Clinical Society of London, 53, Berners Street, January 1878.

"Dear Sir,—The inconvenient effects which occasionally follow the incautious or long-continued use of the hydrate of chloral have induced the Clinical Society to appoint a Committee for the purpose of investigating certain points in the action of this important drug. The scope of the inquiry has been defined within the following limits: 'To investigate what deleterious effects follow the prolonged and continuous use of chloral in ordinary doses.'

"The Committee consists of Sir William Jenner, Bart., Dr. Andrew Clark, Dr. Buzzard, Dr. Duckworth, Dr. Barlow, and Dr. Farquharson.

"It is evident that a report upon such a subject will be valuable in proportion to the number and accuracy of the observations upon which it is based; and, in entering upon its task, the Committee therefore invites the co-operation of the profession at large, and especially of those members of it who enjoy the opportunities afforded by family practice. Every accurately noted fact, even though it be isolated and of little evident utility, will be of service; and, from the mass of evidence which may thus be placed at its disposal, the Committee hope that some generalisation of an useful kind may at least be attempted.

"The enclosed list of questions has been framed with the view of drawing attention to the points most worthy of consideration, and the Committee will feel much obliged by replies to as many of the inquiries as your opportunities of observation enable you to furnish.

"Should it be preferred, however, this column may be left blank, and the information afforded in any other form that may be thought desirable.

"In the event of your being able to favour the Committee with the advantage of your experience, you will oblige by posting the circular to the Honorary Secretary, at the abovementioned address.—We are, dear sir, yours faithfully,

"WILLIAM JENNER, M.D., Chairman.

"ROBERT FARQUHARSON, M.D., Honorary Secretary.

"Results of the Prolonged Use of Chloral.—1. Age. 2. Sex. 3. Temperament, if marked. 4. Occupation, sedentary or otherwise. 5. Habits as regards stimulants. 6. For what purpose was the chloral given. 7. In what doses. 8. For how long, and whether continuously, or with intervals of what duration. 9. If taken continuously for a prolonged period without obvious ill-effects. 10. If use followed by obvious ill-effects in reference to the—A. Nervous; B. Circulatory;

c. Digestive ; D. Cutaneous ; E. Urinary, or other systems. 11. Any further information on any other head, not tabulated, which your experience may afford. (N.B.—Additional schedules will be forwarded on application.)”

### THE BEARING OF EXPERIMENTAL EVIDENCE UPON THE GERM-THEORY OF DISEASE.

SIR,—Dr. Bastian's remarks on the above subject, published in the last number of the *BRITISH MEDICAL JOURNAL*, will receive the attention due to any deliberate statement made by so high an authority. I question, however, if pathologists will be impressed with either the clearness or the cogency of the arguments adduced by Dr. Bastian against the germ-theory of disease ; or will regard as other than rash and unwarranted his statements, “that existing evidence seems abundantly sufficient for the rejection of this doctrine as untrue”, and that “all the distinctive positions of those who advocate a belief in the so-called ‘germ-theory of disease’, or rely upon the exclusive doctrine of a ‘contagium vivum’, seem to be absolutely broken down and refuted”. Before we can be in a position to talk so decidedly and confidently regarding “the distinctive positions of” those who maintain the germ-theory of disease, we must have an intelligent appreciation of what those distinctive positions are.

To understand or appreciate arguments for or against the germ-theory of disease, we must have a clear understanding what that theory is. Till we have this, we cannot see the exact force and bearing of a given argument. What, then, is the germ-theory of disease? This is no unnecessary question ; for, both by its friends and foes, this theory is referred to in the most loose and indefinite manner. Not only by Dr. Bastian, but by many others, the germ-theory of fermentation, and the germ-theory of disease, are treated and written about as parts of one and the same question. It cannot be too strenuously insisted on that the two questions, though allied, are totally distinct and separate ; and that each must stand or fall on its own merits, and independently of the other.

A short statement of what each theory implies will make this apparent. There are two theories as to the mode of production of fermentation. One is the vital theory, according to which living organisms are the sole causes capable of producing fermentative change. The other is the physico-chemical theory, according to which such change may be produced by any organic matter, living or dead, which is undergoing change. All admit the presence of organisms in the fermenting fluid. According to one theory, these organisms are developed from the pre-existing germs whose presence in the fluid gave rise to the fermentative change. According to the other, they are developed *de novo* in the changing fluid.

Such, briefly, are the two opposing views. The question is, not whether living organisms can set agoing fermentation—that is admitted by all—but whether or not living organisms are the sole causes capable of doing so. Of the invariable presence of masses of minute organisms in fermenting fluids there is no doubt. The point of discussion is the source and mode of origin of these organisms. Thus it has come to pass that the discussions which have taken place regarding the mode of production of fermentation (and putrefaction) have really been discussions on the doctrine of spontaneous generation. Those who uphold the germ-theory of fermentation deny the occurrence of heterogenesis, and maintain that all life springs directly from antecedent life. Those who uphold the physico-chemical theory as strenuously maintain the doctrine of heterogenesis.

The germ-theory of fermentation is thus essentially antagonistic to the doctrine of heterogenesis ; and the question with which we are really dealing, when we discuss that theory, is the doctrine of spontaneous generation. It is not so with the germ-theory of disease. This theory is that many diseases (notably epidemic and contagious diseases) result from the propagation in the system of minute organisms having no part or share in its normal economy. It deals simply with the competence of living organisms to produce the phenomena of disease ; and does not necessarily take cognisance of the question, whether or not organisms may originate *de novo*. The germ-theory of disease, therefore, exists on an independent footing ; and would still exist and hold sway, though the physico-chemical theory of fermentation and putrefaction had been proved beyond a doubt. The competence of germs to produce fermentation is admitted by all. The competence of germs to produce the phenomena of disease is the special subject of discussion between the supporters and the opponents of the germ-theory of disease.

I have elsewhere\* shown that the germ-theory affords of the pheno-

\* *The Germ-Theory applied to the Explanation of the Phenomena of Disease* London: 1876.

mena of the specific fevers a more complete and satisfactory explanation than any theory hitherto advanced ; the whole of the phenomena presented by these diseases being quite explicable on the view that millions of minute organisms are being propagated in the system during the period of their continuance. And this is the line of argument to which we must sooner or later come, if we would fulfil the highest duties of our calling.

It is not enough to try to explain why infusions of meat decompose, why wine ferments, and why urine becomes putrid. We are constantly surrounded by ailments whose causation and pathology the germ-theory of disease seeks to explain. People are annually dying of these ailments by tens of thousands. It is the investigation of the phenomena of these diseases, as they present themselves at the bedside and in the *post mortem* room, that should engage the attention of physicians and pathologists. Earnest hard-working men of science are eagerly engaged in investigating the more purely scientific, and, to humanity, less practically useful, question of the germ-theory of fermentation and putrefaction. Let us, as medical men, have an equally keen sense of the importance to our science of the allied question of the germ-theory of disease—a theory which deals with the question of the causation and pathology of the most important ailments to which man is liable. But let us free ourselves at once from the fatal error of supposing that our question is inseparably linked with that of the philosophers, or that we are in any way dependent on them.

There are in our ranks earnest, able, and willing workers enough. Let us only have a clear conception of what we are called upon to do. Let us be alive to the great fact that the subjects of our investigations and inquiries are the phenomena of disease, as they present themselves to our notice at the bedside ; and let us discard for ever the deluding idea that the germ-theory of disease must stand or fall with the germ-theory of fermentation, or that it has even any necessary connection with it.

What has been said affords all the answer that is required to Dr. Bastian's hostile remarks on the germ-theory of disease. The arguments which he brings forward are all meant to support his well-known views on the doctrines of heterogenesis and archebiosis. They have no bearing on the germ-theory of disease. Dr. Bastian refers to the experiments of Drs. Lewis and Cunningham, and of Dr. Burdon Sanderson. It would not be difficult to show that their facts tell more in favour of than against the germ-theory of disease. On a future occasion, I may take the opportunity to do so. In the meantime, as Dr. Bastian merely adduces them “to show that, under certain conditions, low independent forms of life may originate in the midst of living tissues, previously free from them, by a kind of transformation (heterogenesis) of some of the units of protoplasm, which, though still living, have been modified in nature and tendency by reason of their existence in a partially devitalised area”. As this is all that he adduces them for, I shall content myself with pointing out that he is arguing, not against the germ-theory of disease, but in support of the doctrine of heterogenesis ; and that arguments which favour the latter do not necessarily tell against the former.—Your obedient servant,

T. J. MACLAGAN, M.D., Physician to the Dundee Royal Infirmary ;  
Examiner in Medicine to the University of Aberdeen.

### DYSIDROSIS AND CHEIRO-POMPHOLYX : AN EXPLANATION.

SIR,—I beg to be allowed to correct the impression my contribution of December 29th seems to have made upon Mr. Hutchinson's mind. First of all, let me disclaim all intention of implying that the disease was comparatively new to him at the time when he first spoke to me about it. From the manner in which the subject was introduced—not by the presence of an actual illustration of the disease—I, not unnaturally perhaps, concluded that Mr. Hutchinson had not then seen many cases ; but after the publication of his apology in 1876, I was willing to allow any reasonable claims that he or his friends might prefer as to the date and the independence of his observations. From that time, the matter ceased to have any interest for me, until I read Dr. Thin's article in the *BRITISH MEDICAL JOURNAL* of December 1st. That gentleman, while allowing that Dr. Tilbury Fox had published a detailed account of the disease in January 1873, affirmed, on the evidence of the publication in 1876 of a clinical lecture alleged to have been delivered by Mr. Hutchinson to his pupils in 1871, that “as far as published evidence goes” the credit “of having first recognised that there is a distinct and previously undescribed verrucal or bullous disease chiefly attacking the hands” belongs to Mr. Hutchinson. As a protest to this strained judgment, I felt bound, in justice to Dr. Tilbury Fox, to state that as early as the commencement of the year 1870, he

had pointed out to me, and to others of his pupils, the chief characteristics of a bullous eruption occurring on the hands, similar to, if not identical with, that described by Mr. Hutchinson as cheiro-pompholyx. The obvious reply to Dr. Thin is, that if Dr. Tilbury Fox had been as fortunate as Mr. Hutchinson in securing devoted assistants and amanuenses, he would have been able to produce the *ipsissima verba* of his expositions of the year 1870.

I trust that Mr. Hutchinson will perceive that he is mistaken in thinking that I revived the controversy respecting the "priority of observation", and that he will accept the assurance that in referring incidentally to our conversation I was not actuated by the sinister motives he has imputed to me, but with the simple desire to call him to witness that at that time the disease was not new to me.—I am, sir, yours truly,

JOHN TWEEDY.

Harley Street, W., January 12th, 1878.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 11TH, 1878.

CHRISTOPHER HEATH, F.R.C.S., Vice-President, in the Chair.

*Lupus of the Face treated by Linear Scarification aided by Erasion.*—Mr. PALMANN SQUIRE exhibited a woman aged 32, single, a needle-machine worker, who had been affected with lupus of the face since the age of fourteen. The disease appeared first on the nose, and remained restricted to the nose until three years ago, when the disease appeared on the right cheek, also occupying here a distinct position quite isolated from the patch on the nose. Her condition in September 1877 was that the lower third of her nose had disappeared, and become replaced by a thick scab covering an ulcer, the floor of which consisted of pale flabby granulations exuding a thin purulent discharge. The patch of disease on the right cheek measured two inches vertically by an inch and a half horizontally. It consisted of unbroken lupus-tubercles, and presented no scabs or ulcerations. On September 27th, Mr. Squire operated on the whole of the diseased area both of the cheek and of the nose by scraping away the friable portion of the diseased skin by means of a small steel spoon provided with sharp edges, after the manner originally advocated by Dubini of Italy, and subsequently by Volkmann of Halle, and, as soon as the surface had healed, he again, after about a fortnight's interval, repeated the operation. On the surface healing for the second time, a very considerable improvement was noticeable. In fact, the cure of the disease was evidently for the greater part already accomplished. There remained still various portions of skin which, although not sufficiently diseased to permit of their being scraped off by means of the spoon, were, nevertheless, evidently affected in an obvious degree with lupus-infiltration. These accordingly were treated by means of linear scarification repeated at short intervals several times over the same area. The ulcers of the interior of the nostrils were treated in the same manner, namely, by operating through a nasal speculum. The patient did not on any of these occasions avail herself of anaesthesia, either general or local, but bore the process almost without flinching. She seemed now to be quite cured of her disease. The period between the time at which the disease had now long since seemed to be cured; and this present time had been occupied by Mr. Squire in watching to see if any return of the disease took place, and by his eradicating by means of erasion with the sharp spoon or by scarification with the scalpel any minute traces of the disease which seemed to be still left unobliterated. His deviations from the course of his predecessors in this method had consisted in the use of much smaller spoons for the purpose of attaining greater accuracy in manipulation—an important point, when it was requisite to eradicate even the smallest possible remains of the disease, and for the other matter in employing linear scarification in place of the hitherto used and so-called multiple punctiform scarification, equally also for the purpose of attaining greater uniform precision in the treatment.

In reply to the Chairman, Mr. SQUIRE said the nares were affected to the extent of half-an-inch, and that in some instances incising was not enough, scraping being required when the infiltration of leucocytes had proceeded to any depth.—Mr. PICK asked if there had been treatment, as he had seen good results from large doses of arsenic, pushed almost to poisoning. He had never, however, seen perfect healing, as out-patients generally disappeared before that period.—Dr. WHITMAN spoke of a case of lupus, where both local and general treatment had been employed with little success. The woman came one day with her face quite raw on one side from the kick of her child, but the lupus speedily healed. The other side was then cauterised, and that, too,

healed.—Mr. SQUIRE had only used local treatment; and, in reply to a question from Dr. Althaus, said he had used Hebra's treatment with nitrate of silver, but only superficially, whereas Hebra used it deeply. Sometimes, so used, it left a permanent discoloration.

*A Case of Chorea, complicated with Epilepsy, in the Adult Male.*—Dr. ALTHAUS read a paper on this case, which was that of a gentleman, both of whose parents had the neurotic constitution, and had moreover been first cousins. The chorea appeared when the patient was fifteen years of age, there being no history of fright, rheumatism, or endocarditis, the exciting cause having probably been masturbation. After having lasted six years, the St. Vitus's dance became complicated with epileptic attacks, the first one of which occurred after exposure to a powerful sun, and which after a time became numerous, both in the daytime and during sleep. These attacks were peculiar, inasmuch as they could apparently be brought on by a variety of circumstances under the control of the patient, and could also frequently be arrested by other proceedings. The patient was good-humoured, somewhat childish, but very fond of reading. The symptoms of chorea were seen in all the voluntary muscles of the body, there being no difference between the two sides. There was great tendency to general vaso-motor disturbance. Dr. Althaus treated the case with arsenic and bromide of potassium, without result; and, after these medicines had been given for a sufficient time, with various other nerve-tonics and sedatives. Nothing, however, seemed to benefit the patient until, in 1870, hydrate of chloral was given, which greatly checked the restlessness and general convulsibility from which he then suffered, and was also useful in arresting the epileptic fits. The patient unfortunately soon contracted the habit of taking immoderate doses of chloral, and, although the chorea was nearly cured, his digestion and general health became greatly impaired, and the epileptic attacks became more frequent and uncontrollable. He died in 1874, under peculiar circumstances, being found dead in his bed, with a wineglass half full of chloral clasped in his hand; and it was believed at the time that he had died of an overdose of the chloral. Dr. Althaus could not entertain this idea; but argued that, if chloral had killed him, there would have been complete muscular relaxation, and the patient could not have been found several hours after death clenching a glass half full of liquid. He thought that the patient had intended to take chloral for a fit, the symptoms of which were coming on; that he died in the fit before being able to take the chloral, and that rigor mortis, setting in immediately after death, caused the glass to remain clenched in the hand of the patient. Dr. Althaus drew attention to the value of the hydrate of chloral in the treatment of chorea, saying that cases of this disorder in adult males were generally incurable, but that in this case the chorea, which had lasted eighteen years and was severe, was very nearly cured when no other medicine nor the continuous current had made the slightest impression on it. He explained this effect by the theory of chorea being caused by active hyperæmia of the corpora striata and of the territory of the Sylvian arteries generally, while chloral caused anæmia of these structures, and was, therefore, a direct antidote. After some further remarks on the pathology of the case, he discussed the question whether the custom now obtaining in this country of chemists supplying patients with any amount of a powerful medicine like chloral, from a single prescription, should not be checked by legislative interference. In the present case, the patient had procured wholesale supplies of chloral from a West End chemist at a time, and had thus rendered it impossible to regulate the dose. Dr. Althaus alluded to the law of Germany and Austria, that a prescription, after having once been made up, was detained by the apothecary, and could only again be used on the physician once more attaching his initials and the date to it. The present custom in force in England not only enabled patients to do themselves and their friends a great deal of harm, but also opened the door to crime, inasmuch as it rendered the Sale of Poisons Act utterly futile.

Dr. CAYLEY had used chloral in the treatment of chorea, but had not found it very useful, probably as he feared to give it freely to out-patients.—Dr. SOUTHEY had used both chloral and bromide of potassium in two cases, one being very bad. He gave ten grains of each every two hours till sleep was produced; after that, the dose was reduced. Speedy improvement followed.—Mr. SOELBERG WELLS, referring to the subject of prescriptions, mentioned two cases. In one of these, morphia had been ordered in small quantity as an injection under the skin, but the practice was continued till ten or twelve grains a-day were used. He sent the patient to Dr. Levinstein at Berlin, who had treated of this matter (*Morphiumsucht*). In another case, arsenic was the substance used. One day, a very large dose was taken, but the patient was seen at once, and the life saved.—The CHAIRMAN asked if the masturbation was stopped, or any surgical operation done to arrest it. He had often seen blistering do good. He thought the question of epileptics marrying an important one. He had found bromide of potas-

sium the best thing in delirium tremens.—Dr. BURNEY VEO, referring to the marriage of epileptics, mentioned a case where an epileptic attack came on shortly after marriage, which terminated fatally in a few days.—Dr. ALTHAUS, in reply, thought the use of chloral in out-patient practice was not so advantageous as when the patient was under complete control. Chloral and bromide formed a good combination. He thought the prescription question very important.

*Severe Hemorrhage, following Operation for Cleft Palate, Stopped by Plugging the Posterior Palatine Canal.*—Mr. HOWARD MARSH read notes of the case. The patient, a young man aged 23, was admitted into St. Bartholomew's Hospital, where the following operation was performed. The patient being under chloroform, and Mr. T. Smith's gag having been introduced, the edges of the fissure—which involved the soft and the posterior half of the hard palate—were pared. The posterior part of the soft palate and the uvula, there being no tension in these parts, were brought together; then the soft structures were detached from the bone at the sides and anterior extremity of the cleft of the hard palate, and brought together; lastly, lateral cuts, about three quarters of an inch long, were made through the soft parts to relieve all tension on the sutures at the middle line. There was no undue bleeding at the time of the operation, but, three hours afterwards, hæmorrhage to the extent of about half an ounce occurred from the left nostril; this, however, ceased when the palate was syringed through the nose with iced-water. On the fourth day, the palate had all united and the patient was allowed to be up. The same evening, when he had, contrary to orders, eaten a thick crust of bread, blood was found to be dropping quickly from the left nostril and trickling down his fauces. Though arrested for a time by iced-water, the hæmorrhage soon returned; and when Mr. Marsh was called to him, two hours later, he was in a very prostrate state, for he had just vomited fully a pint of blood from the stomach, and was still bleeding quickly from the nose. Imitating a practice followed by Mr. Willett some years since, in a similar case, of plugging the posterior palatine canal, as Mr. Smith had suggested—an experiment which Mr. Willett found completely successful—Mr. Marsh having, by means of a sharp-pointed probe, passed through the lateral cut, found the orifice of the canal (which is situated about a third of an inch anterior to the hamular process of the sphenoid, and about the same distance directly inward from the wisdom-tooth) he passed into the canal a wooden peg, about as big as a common match, and straightened at its end. This was done by holding the peg in a pair of strong forceps with its point directed upwards and somewhat backwards in relation to the roof of the mouth. The bleeding at once ceased; but it returned when the plug slipped out two days later. It was, however, at once stopped when Mr. Schofield, the house-surgeon, reintroduced the peg. All went on well now; and, three days later, the plug again came out, and no bleeding ensued. But, two days later still—that is, fourteen days after the operation, five days after the last bleeding, and forty hours after the plug had come away—the patient was suddenly awoke by renewal of the hæmorrhage. He now bled severely for nearly three hours, in spite of various attempts to arrest the trouble; and, when Mr. Marsh was called to see him, he was found to be in a most dangerous condition of prostration. While he was under chloroform, however, the plug was introduced into the canal, from which blood could be plainly seen to be flowing, and the hæmorrhage, as on the previous occasions, immediately ceased. From this time, there was no return, and the patient soon recovered. The union of the palate remained sound and apparently unaffected by these repeated hæmorrhages. The author drew attention to the amount and very obstinate character, and repeated recurrences of the bleeding in this case, and strongly advised the plugging of the palatine canal in any case of serious hæmorrhage from the palate. The patient manifested severe pain when, by the introduction of the peg, the large posterior palatine nerve accompanying the artery was crushed; but no subsequent permanent trouble had ensued from this nerve-injury.

Mr. MAUNDER said that, although the time of the meeting was short, he could not refrain from congratulating Mr. Smith upon his suggestion, and Mr. Willett and Mr. Marsh upon their successful application of it. There was nothing to cause greater alarm to a patient, or more anxiety to a surgeon, than recurring hæmorrhage. On three occasions he (Mr. Maunder) had been called upon to consider the question of tying the common carotid artery for severe bleeding within the mouth. In one of these, he had ligatured successfully the main artery to arrest dangerous hæmorrhage from the region of the internal maxillary artery. In the other two, milder measures had fortunately sufficed. Surgeons would certainly not forget the useful hint which had been just given them.—Mr. T. SMITH said it was not so difficult to find the canal, as it was possible to feel the vessel pulsate, and then it might be easy to insert a sharp-pointed needle.—Mr. GOULD asked the effect

on the nerve of such pressure as to stop the bleeding.—Mr. HEATH thought the incision indicated in Mr. Marsh's figure was too far back. He preferred to make longitudinal incisions, and then to work backwards and forwards in them. If cut too near the orifice of the canal, the vessel was in a measure bound down.—Mr. BARWELL spoke of a child on whom he had attempted to operate, but was prevented by the hæmorrhage, and this went on for days. Again he tried, but the bleeding came on as before, so that he was obliged to desist. Some time afterwards, the child hurt her foot and bled to death. The whole family, as it turned out, were bleeders.—Mr. MARSH said he had used a sharp probe to discover the orifice of the canal. The bleeding was so bad that the man had serious fainting fits. In the operation, it was often necessary to go near the orifice of the canal. The question of family bleeding ought to be carefully gone into.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: MICROSCOPICAL SECTION.

DECEMBER 21ST, 1877.

W. HINDS, M.D., in the Chair.

*Granular Kidney.*—Dr. SAUNDY showed some specimens to illustrate the pathology of granular kidney. Besides demonstrating the vascular changes, he drew especial attention to the mode in which the renal tubules atrophied; the lining epithelium lost its protoplasm, and became converted into small cells, which gave rise to appearances very like biliary canaliculi. Dr. Saundby remarked that an analogous process took place in cirrhosis of the liver, and showed a specimen of liver taken from the same case, so that the two processes could be compared. He regarded the pathology of the affection in both organs as essentially similar, and as commencing, as all affections of the connective tissue do, around the blood-vessels.

*Parasites.*—Dr. HINDS showed trichophyton tonsurans which he had mounted from cases recently under his care, and which illustrated in a marked manner the direct transmissibility of the disease and its high degree of contagiousness. Although this microphyte was regarded by authors in general as the direct cause of the affection, he considered that there was room for grave doubt; and that, though the contagiousness be admitted, it could hardly follow of necessity that the proximate cause of the disease was the fungus itself. If the special food and the conditions were present, the plant was sure to be produced. While the trichophyton was a mainly a sporulous fungus, and was an essential feature in tinea tonsurans, being always present, it should nevertheless be borne in mind that certain decompositions, or those of certain organic bodies, were often or always characterised by the spontaneous growth of specific fungi.

*Phthirius.*—Dr. HINDS showed a mounted male and female phthirius, found, with some other specimens, upon a gentleman of great respectability and of most cleanly and moral habits, and aged about 42. The specimens inhabited the neck, wrist, etc., only. The patient was of a very sensitive and kindly nature, was subject to occasional attacks of deep depression of spirits, and finally, a few weeks afterwards, committed self-destruction. Mere accident did not appear to account for the presence of these parasites. Dr. Hinds thought that it was probably to be explained by a morbid secretion from the sebaceous follicles and pores, or dirt from within, which attracted and fed the parasite, and gave it a congenial resting-place and a home of luxury.

#### THAMES VALLEY BRANCH.

DECEMBER 18TH, 1877.

W. PRICE JONES, M.D., in the Chair.

*Intussusception in an Infant.*—Dr. HOOVER related a case of intussusception in a child four months old, in which there were constant vomiting and copious discharge of blood-stained mucus, with considerable distension of the abdomen; while in the rectum was felt what appeared to be a cylinder of impacted intestine. At 3 P.M., an injection of soap and water was administered by means of a catheter, and a drop-dose of tincture of opium given. At 6 P.M. the child was free from vomiting or straining, a natural motion was passed, and the child was convalescent in two days.—An interesting discussion ensued in which Drs. WYMAN and JONES and Mr. BATEMAN took part.

*Muco-Enteritis.*—Dr. BATEMAN read a paper on muco-enteritis. He described an ordinary case in a child about seven months old, with a well-marked Hippocratic expression, plaintive wail, and the bowels acting frequently, with almost constant tenesmus and discharge, of at first feculent matter, and afterwards of watery mucus with flakes. There were erythema around the anus, elevation of temperature, etc.

These symptoms continued while either ordinary or Swiss milk, thickened or not, was administered, exhaustion and death terminating the case. Dr. Bateman advanced the opinion that the principal cause was the caseine of the milk upon which the infants are fed, and propounded the question why it should not be produced by the caseine of woman's milk?—A discussion followed, in which Dr. JONES, Dr. WYMAN, Mr. SHIRTLIFF, and Dr. HOOPER took part.—Dr. JONES stated his opinion, as the result of long experience, that the caseine of cow's milk was indigestible only when cows were fed on brewers' or distillers' grains. It was found that by such food the proportion of caseine was increased, and, further, he believed that caseine was in an isomeric and more indigestible state. He mentioned numerous instances in which he put the idea to a critical test, by varying the food of the cow or goat.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### LUNATICS IN WORKHOUSES.

THE Brighton Board of Guardians had before them, at a recent meeting, a question of importance to parochial bodies, which has been brought prominently under consideration by a circular letter from the Bradford Union; namely, the desirability of memorialising the Local Government Board with the view to obtaining an Imperial grant for the maintenance of pauper lunatics, where such persons are housed and provided for within the walls of local workhouses. At present, a grant is made with respect to such male lunatics as are supported in the county asylums; but in many instances, Bradford and Brighton amongst them, efficient accommodation for such cases has been secured in workhouses, without, however, any subsidy being paid for them. The Board unanimously resolved on a memorial to the Local Government Board, pointing out that provision had been made, at great expense, for the maintenance of idiots and chronic lunatics in special wards at the Brighton workhouse, and that upwards of one hundred and twenty-three such cases were actually there at the present time; also, that the cost of such persons was two shillings per week in excess of ordinary inmates; and asking the Local Government Board to take the subject into consideration with a view to ending the inequality in the matter. As it was understood that other Boards were taking steps to memorialise the Board with the same object, it was decided to await their action before presenting the present memorial.

### THE BROMYARD GUARDIANS AND MEDICAL EXTRAS.

FROM *Perrod's Worcester Journal* of the 5th instant, we learn that, at a recent meeting of the Bromyard Board of Guardians, the Chairman—Sir Robert Harrington, Bart.—brought up the report of the Committee appointed, in September last, to inquire into the amount and nature of the medical extras ordered in District No. 1, containing a population of 6,581 and an area in acres of 32,979. The Committee reported that not only was there a larger number of cases in receipt of medical extras in this district than in either of the other two, but that the medical officer gave an uniform order for three pounds of meat weekly, instead of two as ordered by his colleagues; that they had called on Mr. Powell for an explanation, who had stated that, if the number of cases in his district in which he had ordered extras exceeded that in the other two districts, it was because he had received orders to attend a larger number of cases, which was accounted for by the fact that the population of his district exceeded that of the other two districts. (We perceive, by the last census, that the united population of the other two districts amounts to 5,353, and the united area to 28,028 acres). He also pointed out "that two-thirds of the patients had been over sixty years of age, and that the majority of the cases were those of malnutrition or chronic starvation (infirmary), and that if such patients had been supplied with, or had had the means of supplying themselves with, a better kind of diet, they would probably not have sought an order for medical relief; that he had ordered for each case on its merits, and the Committee must not expect that he should be guided by the practice of the other medical officers, or that they should be guided by any treatment adopted by him". He also showed that the meat supplied consisted of breasts, necks, and scrag-ends of necks, and that, when the bone was extracted, the amount left available for food was about equivalent to the dietary in use in the workhouse.

Taken aback by this remarkably cogent and conclusive reply, the

Committee recommended that the master and matron should receive stringent orders to act, in all cases, on the rule of retaining the bony portions of the meat in the house for soup, and delivering the best and least bony portions of the meat to out-patients; that no difference in this particular should be made in either of the districts; and that the relieving officers, medical officers, and guardians should be invited to inquire into and report whether this was done. At the same time, it was decided that the clerk shall, by way of reminder, send to the medical officers a copy of the rule bearing on the ordering of extra medical relief, the purport of which is that the out-door medical officer can only recommend, but not order, medical extras, the responsibility of complying with the recommendation being thrown on the relieving officer.

The subject of ordering and the supply of medical extras to the infirm and sick poor is one of great importance in rural districts; and we urge that a very considerable amount of latitude should be conceded to the medical officer in issuing his recommendations to the relieving officer on this subject, for there can be no question that the maintenance of the very life even of the aged and infirm is mainly dependent on the supply of properly nutritious food; and, if this be correct of these classes, it is even of still more importance when the patient is young, or when the bread-winner has been stricken down by illness, and needs a generous dietary to restore him to health and work. Feeling this to be the case, we consider that the best thanks of the service and the public are due to Mr. Powell for the able and manly stand he has made against the attempt of the Bromyard Board to fetter and obstruct him in the righteous performance of his duty.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, January 10th, 1878.

Fergusson, Reginald Archibald, Ronald Street, Glasgow  
Maybury, Lysander, Frimley, Surrey  
Roper, George Arthur, Denmark Road, Camberwell

The following gentlemen also on the same day passed their primary professional examination.

Blackwell, Frederick William, London Hospital  
Green, Harry, General Hospital, Birmingham

### MEDICAL VACANCIES.

THE following vacancies are announced:—

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.**—Assistant-Physician. Applications to be made on or before the 26th instant.

**DURHAM COUNTY HOSPITAL.**—House-Surgeon. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 26th instant.

**IPSWICH BOROUGH LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.

**KENT COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer and Dispenser. Salary, £165 per annum, with furnished apartments, milk, vegetables, washing, and attendance. Applications to be made on or before February 6th.

**LIMERICK UNION.**—Resident Medical Officer of the Workhouse. Salary, £200 a year, with apartments, rations, etc. Applications up to the 30th instant.

**LOUGHBOROUGH DISPENSARY AND INFIRMARY.**—Resident House-Surgeon. Salary, 100 guineas per annum, with furnished rooms, fire, lighting, and attendance. Applications to be made on or before the 26th instant.

**NEWCASTLE-UPON-TYNE INFIRMARY.**—Senior House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before February 4th.

**RADCLIFFE INFIRMARY, Oxford.**—Surgeon. Applications to be made on or before the 29th instant.

**ST. JOHN'S HOSPITAL FOR SKIN-DISEASES.**—Honorary Medical Officer. Applications to be made on or before the 21st instant.

**SCARBOROUGH DISPENSARY AND ACCIDENT HOSPITAL.**—House-Surgeon and Secretary. Salary, £120 per annum, with apartments, coals, gas, and attendance. Applications to be made on or before the 21st instant.

**SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY.**—Senior House-Surgeon. Salary to commence at £80 per annum, with board and residence. Applications to be made on or before the 24th instant.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

DAVIES, H. W., M.R.C.S. Eng., appointed House-Surgeon to the Memorial Hospital, Jarrow-on-Tyne, *vice* J. E. Emmerson, M.B., resigned.

\*PARKER, Rushton, F.R.C.S., B.S., appointed Assistant Surgeon to the Royal Infirmary, Liverpool, *vice* W. M. Banks, M.D., appointed Surgeon.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

#### DEATH.

EASTON.—On December 27th, 1877, at 19, Norfolk Crescent, Hyde Park. Eleanor Margaret, eldest daughter of \*John Easton, M.D.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY**..... Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY**..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY**..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY**..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY**..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY**..... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**—Medical Society of London, 8.30 P.M. Lettsomian Lecture by Francis Mason, F.R.C.S.; subject, "The Surgery of the Face".

**TUESDAY**—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. C. Higgins, "On a Case of Rodent Ulcer"; Dr. George Thin, "On the Proportion of Red Corpuscles in the Blood in some Skin Diseases"; Dr. John Harley, "A Second Communication on Simple Atrophic Sclerema".

**WEDNESDAY**—Hunterian Society, 7 P.M.; Council Meeting, 8 P.M.; Open Meeting.

**FRIDAY**—Clinical Society of London, 8.30 P.M. Mr. Pearce Gould, "A Case of Spina Bifida cured by Injection of Iodine" (a living subject); Mr. Berkeley Hill, "Cases of Spinal Curvature treated by Sayre's Plaster-Jacket" (giving subjects); Mr. Nunn, "Two Cases of Cancer of the Breast"; Dr. Broadbent, "A Case of Paracanthosis Thoracis"; Quekett Microscopical Club, 8 P.M. Mr. T. Charters White, "On Insect Dissection".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

The following communications have been handed to the General Manager:—Mr. W. Hasler (Kilbenny); Mr. Howgrave Graham (Enfield), with enclosure; Mr. J. Herbert Mearns (Richmond, York); Miss King (Southfield); Mr. C. Taylor (London); Mr. G. Rice (Woolwich); Mr. W. T. Grant (Birmingham); Mr. W. M. Banks (Liverpool).

## THE PROPER TREATMENT OF APPOXY.

**SIR**,—My attention has only just been directed to an article in your *JOURNAL* of the 5th instant, headed "The Proper Treatment of Apoplexy." As I am the person therein alluded to as having instigated the charge against Dr. Bates, I beg to give this statement (which is apparently given solely on the authority of a local newspaper) my most emphatic denial. Although some difference of opinion existed between me and Dr. Bates as to the treatment of the case in question, I neither originated the attack against him, nor was I aware, until I read the report in a local paper, that any charge was even contemplated against this gentleman. I may add that no one regrets more than I do the undue publicity given to the case to which your article refers, such a course being calculated to promote ill-feeling amongst members of the profession.—I am, sir, yours, etc.,

T. D. STANISTREET, L.R.C.S. & P. Edin.

Cowbridge, January 12th, 1878.

**DR. GEORGE BIRT**.—Our correspondent probably means Rogers's Portable Disinfecting Chest, which contains an outer and inner coating of iron round the bottom and four sides. The fire-box is made movable when the required temperature of 220 to 240 deg. is reached, recognised by a thermometer graduated up to 300 deg. Fahr. It is placed on wheels, to facilitate its removal from one place to another. The price varies from £10 to £30, and it can be obtained of Mr. Charles Rogers, East Retford, Notts.

**NOTICE TO ADVERTISERS**.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

## SAYRE'S TREATMENT OF SPINAL CLEAVATURE.

**SIR**.—Having in July 1877, while in New York, had a month's practical experience with Dr. Sayre of his method of treating spinal curvatures, I may perhaps be pardoned for making a few remarks on the first case of these recorded by Mr. Parker in last week's *JOURNAL*. It is stated that, after the application of the jacket, the child was kept in bed a few days, in order to give it time to dry. Now, the object of his method of treatment, as in hip and knee-joint diseases, is to prevent the patient from being kept in bed, or even in the house, that he may take exercise in the open air the same as ordinary individuals. Dr. Sayre remarks, "Give the patient as little medicine and as much sunning as possible." I think if Mr. Parker put up his patients in a room where the temperature is at about 60 deg., and, after the jacket is applied, carefully lay the patient on a flat cushion or couch, the curiass will be sufficiently firm and dry in half an hour. A heated circular roller now applied over the whole surface will greatly hasten the process. I would recommend also that the plaster be baked in an oven just previously to use, and that the bandages be kept in a tin box, with tightly fitting lid. If the skin-jacket fits, and the dinner-pad be used, I think there would not be any necessity for using cotton-wool or plaster, which is apt to become hardened and displaced, inflaming the skin and causing the curiass to become loosened. From first to last, the patient should not feel the least discomfort, but the contrary; if so, the jacket should be immediately removed and a fresh one adjusted.

As Mr. Parker observes in Case II, the "jury-mast" is undoubtedly highly essential in all cases of cervical disease.—Yours truly,  
GEN. CHAS. CILES,  
30, Great Cornhill Street, January 7th, 1878.

**DR. SAMUEL LEARY** (Berbice, British Guiana).—Letter and enclosure.

## MALFORMATION.

**SIR**.—The following may be of interest to the readers of the *JOURNAL*. N., a delicate woman, was delivered of her first child at the commencement of the seventh month of pregnancy. The child (dead, of course) presented the following malformation. The great toe of the right foot was prolonged into a tendril-like appendage two inches long, not thicker than a small bristle; this had encircled the left leg immediately above the ankle so tightly, that the foot was almost completely amputated at that point. The child was in every other respect well developed.

In the third month of pregnancy, this lady was most seriously alarmed one night by a violent storm of thunder and lightning close to her house, which occupied a very exposed situation.—I am, sir, your obedient servant,  
L.R.C.P.

**DR. W. B. MURPHY** writes, in reply to Mr. Balding, that the age of his patient with tibial aneurism was 25.

## INQUEST AT CATERHAM ASYLUM.

**SIR**.—I can only express regret that you have not seen fit to publish the letters of Dr. Corrie and myself; but surely the common sense of fairness requires you to state in your *JOURNAL* not that the original strongly censoring paragraph which appeared in your columns on the above subject, and which remains unexplained and uncontradicted, was put there after carefully considering the statements on both sides—for up to that time no communication had been made on the subject to you from the asylum—but the contrary. The verdict after an adjourned inquest in the case in question, which you already know, as well as in another adjourned case which has taken place since—viz., "Died from bronchopneumonia, accelerated by removal from the workhouse to the asylum", shows not only the necessity which exists for such action on the part of the management of the asylum, but justifies it in every particular.—I am, sir, your obedient servant,  
JAMES ADAM, M.D., Medical Superintendent.

Caterham Asylum, Caterham, Surrey, January 26th, 1878.

\*.—We have twice gone through the papers on both sides, and adhere to our original opinion, which is adverse to the course pursued, and to the evidence given and the verdict obtained.

## AN OFFICIOUS PATIENT.

**SIR**.—I attend a peculiar patient, inasmuch as I am not allowed to dispense my own medicine nor write a prescription for the chemist to make up. He refers making it up himself, though he possesses very little knowledge of the *Pharmacopoeia*. When I am sent for, I am not allowed, in a manner, to undertake the management of the case, for he is afraid I may make too many visits. I suppose, therefore, it is always a case of "I will send for you if the patient be not better." I was once sent for to a child with a wound of the leg, which required to be nicely dressed. After dressing it once, my services were dispensed with, but I was sent for in about a week to find that the wound had never been dressed, had festered, and the edges were inflamed and gaping. I feel in a very awkward position. What is my duty under such circumstances?—I remain, yours very respectfully,  
J. L. T.

\*.—Why not decline to attend unless full confidence is given, and necessary control? A medical man is not called to solve puzzles in disease, or to answer questions, but to cure; and if all the reasonable conditions are laid out, and fully placed in his power, may fairly decline the responsibility of the case altogether.

## MR. STAMFORD'S CASE OF VILLUS DISSEMINATED OVER PERITONEUM.

**SIR**.—The case narrated by Mr. Stamford of Tottenham, W., in the *JOURNAL* of January 5th appears open to dispute. Here was a case of villous disease of the bladder, and the case is alluded to by Mr. Stamford as being the case of the bladder; but his friend Mr. W. H. Rix thought the villous change probably came from the prostate. We are left at present at a loss as to which of the two surgeons formed these opinions, although I am informed, from the statement of the patient, that the case is one of villous disease of the bladder. Mr. Stamford suggests that he lacerated or injured the urethra during catheterism, and possibly he is correct in attributing the rise to this cause. Although it appears that it was necessary to relieve the bladder by catheterism, I question whether it was wise to leave the catheter in the bladder. Perhaps Mr. Stamford or Mr. Rix would kindly supply some further information upon the case, and state what is the man's present condition, now six months after the treatment. I am, sir, yours, etc.,  
L.R.C.P. Lond.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### THE ABERDEEN MUTUAL ASSURANCE SOCIETY.

**SIR**.—In your number of the 29th ultimo, an anonymous correspondent, subscribing himself "Not a Court-Surgeon and Club-Doctor", calls attention to the affairs of the Aberdeen Mutual Assurance and Friendly Society. The directors of the Society, in justice to their medical officer, consider it but fair that the facts should be known, and have authorised me to state them. In October 1831, the Society was formed to encourage prudence, providence, and self-help, by way of "health and life-assurance", with a limited number of members (now about eighty), almost wholly belonging to the operative classes. The present medical attendant was offered the appointment, and his acceptance of it at the time was considered of great advantage to the Society. Notwithstanding the eminence attained by him in his profession, he has given the benefit of his advice to the members during the last thirty-seven years. The directors are satisfied that, in continuing as medical officer, he has been actuated chiefly by a reluctance to break off early professional ties, and by a desire to give specially to the earlier members the benefit of his advice in their declining years. The remuneration, fixed thirty-seven years ago, by way of small uniform contribution from members, has never been increased; and the yearly total (now about £10) is surely too trifling to excite envy or ill feeling.

The directors are unable to see that they have done injury to any one, looking to the well known fact that in Aberdeen, as in other provincial towns in Scotland, there is no distinction made between the "consultant" and the "general practitioner". In Aberdeen, there is no physician or surgeon who is a pure consultant, and there is no general practitioner who is not occasionally called into consultation—I am, sir, your most obedient servant,

JOHN CROMBIE, Secretary.

**J. G. H. (Great Malvern)**.—The medical bath establishment in Baker Street is still carried on, but under other management, which has tended to improve it considerably.

**MR. WALLROTH** appears to place his proposed society (the Universal Society for the Prevention and Cure of Intoxication and Dipsomania) on an objectionable basis—namely, for the purpose of employing certain valuable receipts of which he alleges himself to be in possession. Medical recipes for relieving the craving for drink of great value have been published by many eminent physicians—Dr. Marcet, F.R.S., Dr. T. L. Bruntton, F.R.S., and others—and if Mr. Wallroth has any further information to contribute, he had better do so: there is no very great need of a society for the purpose. We observe, however, that in one paragraph of the prospectus, in which he seeks for subscriptions, he states that "the cure by the society will be varied according to constitution; and it does not pretend to know any secret medicine or to have found out anything new (as the shameless tribe of quacks always do); on the contrary, the recipes have been tested and proved to be efficacious nearly a hundred years ago; but, alas! the public in general is not sufficiently aware that this evil is easily to be checked". In another part elsewhere we find that Post Office orders are made payable to Mr. Wallroth as manager of the society, that subscriptions and donations are solicited, and agents wanted. We do not see the names of any other persons who are to be responsible for the application of the funds or for the management of the society. Under all these circumstances, we think that philanthropic persons should be very careful in contributing funds to such an enterprise. If Mr. Wallroth be looking to the benefit of others rather than himself, he is taking the worst possible means to secure the result.

**SIR**.—Can you inform me, in the next number of the *BRITISH MEDICAL JOURNAL*, if there are, in Edinburgh, any private medical tutors who prepare candidates for the examination of the College of Physicians of that city?—I am, sir, yours truly,  
January 1878. ENQUIRE.

#### DIPHTHERIA.

**SIR**.—It is to be regretted that your correspondents Mr. Walter Lattey, in the *JOURNAL* of the 12th instant, and Dr. Maunsell, in the number of the 5th instant, have not yet arrived at more definite conclusions respecting the relations existing between the so-called "croup" and diphtheria. Dr. George Johnson's lecture, alluded to by Dr. Maunsell (*BRITISH MEDICAL JOURNAL*, September 15th, 1875), explains the matter clearly enough; and I would point out a letter by myself in the *JOURNAL* (April 1st, 1876, p. 431), in which, I think, the question is also fully explained. If Dr. Maunsell and Mr. Lattey would carefully read these two communications (to say nothing of Sir William Jenner's lecture on the same subject in the *Lancet* at the beginning of 1875), they cannot fail to see that, under the name of "croup", at least two totally different diseases have been hitherto confounded together—namely (1), acute tracheitis, or, more correctly, as Dr. Maunsell suggests, acute laryngo-tracheitis; and (2) laryngo-tracheal diphtheria. In the first, there are all the symptoms and the results of a common inflammation of the air-passages—namely, fever, cough, difficult breathing, redness and congestion of the mucous membrane, increased secretion of mucus; in the second, there is a false membrane, which is the very essence of the malady. The first disease is very tractable, and not often fatal; the second is dreadfully fatal, destroying more than half of the persons attacked. The first is caused by the ordinary conditions, giving rise to inflammation of the respiratory passages, such as cold winds, exposure to vicissitudes of weather, the winter season, etc.; the second is a specific disease, arising generally from contagion or infection, like typhoid fever or scarlatina. Dr. Maunsell's case, which he treated so well and so successfully, was, as he states, one of acute laryngo-tracheitis, and certainly not laryngo-tracheal diphtheria. Mr. Lattey, in attributing to Dr. George Johnson the opinion that croup and diphtheria are the same, must have read Dr. Johnson's lecture imperfectly. What Dr. Johnson has said, and what I have said and written repeatedly, is not that croup and diphtheria are the same, but that what is called "membranous croup" is identical with laryngo-tracheal diphtheria. The evidence that these two latter are the same is overwhelming, and it seems to be as much a waste of time to attempt to discover points of difference between them as it would be to point out the difference between typhoid fever and enteric fever. If Dr. Maunsell and Mr. Lattey would get rid of the word "croup" altogether, and designate by appropriate names the diseases hitherto confounded under it, all the difficulties under which they now seem to labour would disappear. Croup means nothing at all except roughness of breathing, and has no more pathological significance than the old word "cynanche", which was formerly made to do duty for all diseases of the throat and air-passages.—I am, etc.,  
R. H. SEMPLE, M.D., F.R.C.P.L.

8, Torrington Square, January 15th, 1878.

**M. E. P.** appears to us to have acted in a straightforward, honourable, and professional manner. We see no reason to object to his private lithographed note.

**NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

#### AN INDIAN GUIDE.

**SIR**.—With reference to Mr. Lennox Browne's inquiry about an "Indian Guide", will you allow me to mention two works—viz., 1. *The European in India; or, Anglo-Indian's Aide-Memoir*, by Edmund C. P. Hull; to which is added *A Medical Guide for Anglo-Indians*, by R. S. Mair, M.D., F.R.C.S.E., late Deputy Coroner for Madras; published by H. S. King and Co., Cornhill. The price is a few shillings. The addition may be obtained alone, for 2s. 6d. 2. *A Manual of Family Medicine for India*, by W. J. Moore, Bengal Medical Establishment; J. and A. Churchill, London. Price (I think) five or six shillings. This latter book was published by order of the Government of India, who, recognising the utility of such a publication to residents in localities far removed from medical aid, offered one thousand rupees for the best treatise on the subject. Of more than forty competitors, Dr. Moore was the successful one; and, for the purpose for which it was designed, the work is undoubtedly admirably suited. But it is better adapted for residents in India; whereas the *Aide-Memoir*, by Hull and Mair, gives not only similar information, but what is generally useful to the intending emigrant. I recommend both; but if I were required to choose between the two books, I should unhesitatingly select the first.—Faithfully yours,  
C. R. FRANCIS, M.B.,  
Sutton, Surrey, January 16th, 1878. Surgeon-General.

**H. L. S.**—We do not see that H. L. S. can persist in refusing to furnish particulars, unless he is prepared to forego his claim. It is at least certain that he could not enforce his claim in a court of law except by producing items.

#### INFECTIOUS DISEASES IN THE FAMILIES OF MEDICAL MEN.

**H. C. B. (L.R.C.P.)** begs to say, in reply to "Young M.D.", that from inquiries made in his neighbourhood of medical friends, the opinion is strongly in favour of exemption of medical men's families from infectious diseases.

**DR. MANSON (Darlington)**.—The subject shall have attention next week.

The communications of Dr. Newman (Stamford), and others, stand over for want of space.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Masbro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; etc.

\* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

#### COMMUNICATIONS, LETTERS, etc., have been received from:—

Mr. Savory, London; Dr. J. B. Bradbury, Cambridge; Dr. Sanderson, London; Dr. Collie, Homerton; Mr. C. Taylor, London; Mr. Griffiths, Swansea; Mr. G. E. Wherry, Cambridge; Dr. Leeper, Dublin; The Secretary of the Hunterian Society; Mr. H. F. O. Liddell, London; Mr. Wm. Haslar, Killiney; Mr. John Crombie, Aberdeen; Mr. Tweedy, London; Mr. Berkeley Hill, London; Mr. T. D. Stanistreet, Cowbridge; The Secretary of the Liverpool Medical Institution; Mr. Rushton Parker, Liverpool; Dr. Playfair, London; Dr. Boyd Mushet, Birkenhead; Dr. Sawyer, Birmingham; Our Paris Correspondent; Dr. F. Warner, London; Dr. Hitchcock, Lewisham; The Secretary of the Obstetrical Society; Dr. Balthazar Foster, Birmingham; Mr. John Simon, London; Mr. G. Miles, Plympton; The Secretary of the Medical Society of London; Dr. Macnaughton Jones, Cork; N.: The Secretary of Apothecaries' Hall; Dr. Levinge, Stapleton; The Registrar-General of England; Mr. T. S. Ellis, Gloucester; The Registrar-General of Ireland; Dr. J. Milner-Fothergill, London; Dr. Farquharson, London; Mr. T. Holmes, London; Dr. Fairlie Clarke, Southborough; Mr. W. J. Ward, Wortley Grange; Mr. H. C. Boufflower, Tunbridge Wells; Mr. Lattey, Southam; Dr. Murphy, Sunderland; Dr. MacLagan, Dundee; Dr. W. C. Wicks, Newcastle-upon-Tyne; Mr. J. G. Howell, Great Malvern; Mr. W. S. Paget, Great Crosby; M.D.: Mr. Balmano Squire, London; Mr. Reginald Harrison, Liverpool; Dr. A. S. # LECTURES ON THE INFECTIVE PROCESSES OF DISEASE.

*Delivered in the Theatre of the University of London.*

By J. BURDON SANDERSON, M.D., LL.D., F.R.S.,  
Professor of Physiology in University College; and Superintendent of the Brown  
Institution.

## LECTURE III.—*Pathology of Septicæmia (continued).*

I WILL now ask you to allow me to bring together the conclusions at which we have up to this point arrived, in order that we may ascertain what is still required to enable us to understand the relation between the process of putrefaction as it is known to the chemist and physicist, with its morphological accompaniments, bacteria, and the pathological result in which we are so much interested, septicæmia. We have seen, first, that the septic virus is exclusively a product of the vegetation of bacteria—that it can no more come into existence independently of these organisms than the ferment\* or enzyme of the stomach or pancreas can be formed without the secreting structures to which each belongs; secondly, that the bacteria which so generate the virus are incapable of carrying on or continuing the process in the healthy human or animal organism; and finally, that the most important pathological effects of septic poisoning may be explained and accounted for on the supposition that it determines the disintegration of the leucocytes of the blood. We are now prepared to examine another set of facts which have a bearing on the question of the alleged pathogenic action of bacteria; namely, those which show what happens to those organisms when, by accident or design, they find their way into the tissues or the blood. It is not until we have done this, that we shall be in a position to form an opinion in how far we are justified in speaking of them as causes of disease.

Four years ago,† we fully considered the question of the channels by which bacteria enter the animal or human organism. We then saw what an open doorway the absorbent apparatus of the mucous membrane of the small intestine affords for the purpose. I placed before you the experimental proofs that bacteria certainly do enter the organism constantly by the lacteals, and also by the pulmonary mucous membrane. That they enter the healthy body in any other way, cannot be asserted. It may, however, be considered certain that they may enter by any recent wound or traumatic surface, as, for example, by the uterine surface after delivery. I also brought before you experiments showing that, in the healthy state of the animal body, the circulating blood never contains septic bacteria or their germs; the proof being that it is always possible, if blood be received from an artery or vein into a calcined tube, to preserve it without putrefactive change for an indefinite period.

I will take these facts as proved, and content myself with corroborating the evidence they afford by new ones bearing on the same subject. In order to make it perfectly clear that bacteria or their germs may exist in the animal body without in any way interfering with health, I will refer to an experiment which I have several times made.‡ It consists in killing a healthy animal (a rabbit) and rapidly opening the abdominal cavity, cutting out the liver and kidneys with perfectly pure instruments, and allowing each organ to drop without a moment's

delay into a basin previously prepared, containing fused paraffine at the temperature of 110 deg. C. (230 deg. Fahr.) As soon as the mass has solidified, its surface is covered with Venice turpentine, in order to provide against the possibility of contamination by the cracking which is apt to occur in cooling. In some instances, the experiment was varied by substituting oil at the same temperature for the paraffine. Whichever of these plans is adopted, the organ, be it liver, kidney, or heart, by its greater specific gravity sinks to the bottom. If, after a day or two, it be removed and cut into, it is found that its internal surface is firm and opaque, in consequence of the action upon it of the hot paraffine or oil, but that the interior still retains its red colour, a proof that, notwithstanding the very high temperature of the paraffine, that of the central kernel of the immersed organ can never have much exceeded the coagulation point of albumin. Under the conditions I have described to you, it seems to me quite impossible to suppose either that germs could penetrate to the organ from the outside, or that any germ encountered by the organ in its transference from the body of the animal to the basin, could escape destruction. If, therefore, bacteria be found, they or their germs must have been there before the organ was plunged into the hot liquid.

The results of all the experiments, whether with liver or kidneys, was the same. The soft red kernel of uncooked tissue at the middle of the organ always contained bacteria, the vigorous development of which was indicated by their large size, countless numbers, and active movements. To my own mind, the experiment is conclusive. It proves that, in each of the organs experimented on, germs were present during life. If this be so, why did they not grow and multiply? I believe that the question cannot be answered consistently with the germ-theory,\* provided that theory is to be understood in the sense in which I stated it to you at the beginning of this lecture. If it be said that the animal is a rabbit, and that you cannot argue from a rabbit to a human being, I answer that only increases the difficulty; for it is certain that under pathological conditions bacteria grow with great facility, not only in the tissues, but even in the blood of these animals. If, therefore, it be true that septic germs are capable of developing at all in the healthy organism, they ought to develop with special facility in the bodies of rodents; for it will hardly be suggested that, if these animals had not been killed, the germs which were present in their livers would have germinated. There are, therefore, two possibilities open to us. What is observed is (1) that by means of the portal circulation, germs must be continually entering the general blood-stream; and (2) that no bacteria exist in the circulating blood, or at all events only a stray one here and there. The alternatives are: either that the bacteria are formed and are immediately afterwards destroyed (for no provision exists in the organism for their elimination), or that they are not allowed to germinate, *i. e.*, that the conditions under which they are placed in the living organism are such as to prevent their development. The question, which of these alternatives is the true one, I shall not attempt to answer definitively. There are, however, considerations which seem to me to render the first of them more probable than the second. Certain recent and extremely beautiful experiments of Professor Tyndall have shown that comparatively low temperatures, when discontinuously and repeatedly applied, *coup sur coup*, have the power of gradually destroying the germinating power of a liquid, *i. e.*, of rendering it sterile. Now, evidently this is a case which resembles that of the germs continually delivered into the blood-stream of a living animal. Professor Tyndall explains it by supposing that a period of latency intervenes between the germ state and that of the finished organism, during which the germ particles are being prepared for their emergence into fully-formed bacteria. The same thing may very possibly happen in the organism. The germinal material may be allowed just to spring into activity in order to be at once destroyed. The reason why I think this probable is that, when I collect blood (with the precautions that were so admirably described to us last night at the Pathological Society), I find, as Mr. Lister and others have found, that it is sterile. I must, therefore, suppose that germs are not normally present in the blood. Now, inasmuch as material which has been proved by experiment to be so extremely resistant, as germinal stuff has been shown to be by Professor Tyndall's experiments, is not likely to be destroyed while in the germ-state in the circulation, it is not at all improbable that its fate is comparable to that of the germs which are destroyed by the discontinuous application of heat. It is allowed to live in order that it may die.

All of this, of course, is mere speculation. We have no means of observing what happens. The one fact that is certain is, that the

\* See the enunciation of the "germ-theory" at the beginning of the lecture. I am well aware that it is possible to attach great importance to the exclusion of germs, without holding the extreme view that the intrusion of a single septic germ, or of any moderate number of them, can of itself be the determining cause of disease.

\* In order to get rid of the confusion which often arises from the employment of the word "ferment" in different senses, Kühne proposed, in the first of the elaborate series of papers he has lately published on the action of the digestive ferments, to designate "the unorganised ferments, which act in the absence of organisms"—enzymes. See Kühne, "Ueber das Verhalten verschiedener organisirter und sog. unorganisierter Fermente"; *Verhand. der naturhist. med. Vereins zu Heidelberg*, 1876, p. 190.

† See BRITISH MEDICAL JOURNAL, February 13th, 1875.

‡ It is necessary to explain that this mode of investigation is not mine. The method was employed by Dr. Tiegell in Professor Kühne's laboratory in 1874, and described by him in a paper in the 6th volume of Virchow's *Archiv*. He investigated not merely the liver, but the pancreas, spleen, salivary glands, lymphatic glands, and other organs; but it was in the three first mentioned that he obtained the most conclusive proofs of fertility. About the same time, similar observations were made by Professor Billroth, of which an account will be found in his work already quoted (*Coccobacteria*, pp. 26, et seq.). In my own experiments, made in 1874, I followed Dr. Tiegell; but in repeating them, with the kind aid of my friend Dr. Roy, last autumn, I adopted what I thought a better method.

common septic bacteria cannot live in the circulating blood of a healthy animal. Why is this? Various explanations have been given of it. It has been attributed to the alkalinity of the blood, to the want of oxygen, to the excess of oxygen, to the struggle for existence between the blood-corpuscles and the bacteria. The suggestion that it is due to the excess of oxygen is groundless; for in the circulating blood the quantity of free oxygen present is not more than a quarter of the quantity that can be pumped out of this same volume of water freely exposed to the air.\* Nor is it dependent on defect of oxygen; for recent experiments have shown that bacteria continue to vegetate, though slowly, in the entire absence of oxygen. As regards the third suggestion, that bacteria are destroyed in the struggle for existence, it is difficult to criticise it till we know what is meant. I confess I do not understand the analogy which is implied in the expression.†

In connection with the fact that germs are met with in the liver and other abdominal organs, I would remind you of another which clearly stands in relation with it: the observation which has been referred to by Dr. Bastian in his published writings (and was adverted to by him in his observations at the Pathological Society last evening), that, in peritoneal and pleural inflammations in rodents, however produced, it invariably happens that the exudation-liquids contain swarms of bacteria.‡

There are two cases in which this result presents itself: the first, in which in the course of a general infection, which may happen to be of a specific kind, the serous membranes become secondarily inflamed; the other, in which a traumatic inflammation is produced by the introduction of a drop or two of an irritating liquid. If this liquid be, as in the original experiment, itself a germicide, it is clear that no germs can come from outside with it. Obviously, here you have virtually an occluded wound, in which a traumatic inflammation is set up of an infective character. I do not doubt that the germs in this case come in from the intestine; but it is no less certain that they would be utterly harmless, unless the substratum for their development existed in the development of the inflammatory process.

I will conclude by drawing your attention once more to an experimental fact, to which, if I mistake not, I adverted to in my Lectures of 1873. I refer to an experiment made by my friend, Professor Chauveau§ for the purpose of illustrating the influence of blood-contamination—in short, of the septicæmic state—as the progress of traumatic inflammation. It is well known that, among the many operations which are daily inflicted on animals for the purpose of adapting them to the requirements of human luxury, there is one known as *bistournage*, which is largely employed in certain countries. This consists in twisting the spermatic cord, without making any external wound, in such a way that the circulation in the organ is permanently stopped. Of the thousands of operations of this sort which are daily performed, none are ever followed by infective consequences. The organ becomes encapsuled, and eventually shrivels. But if, previously to the operation, a dose of septic matter have been introduced into blood-stream, what happens then? The textures around the organ become the seat of acute diffuse inflammation, which soon extends to adjoining parts, and may threaten life. What is the meaning of this? In the thousands of animals that undergo *bistournage*, without suffering from it, the result is but a counterpart of what happens in a wound when entirely protected from contamination. In the single case, which is infected, a poison present in the blood-stream determines in the injured part an infective inflammation. The experiment affords a striking instance of

the co-operation of two agencies in one pathological process; both of which agencies, although not affecting the result with equal directness, were alike essential. The immediate cause of the septic inflammation of the testicle was evidently the injury to which it had been subjected; but no infective process would have developed itself—nay more, no inflammation whatever would have occurred—had it not been that masses of septic matter were at the time of the injury circulating in the blood-stream, some of which were conveyed to the injured part, and then became centres of infective action.

On the other hand, the constitutional effects which were produced by the injection of the septic liquid into the blood would have passed off without endangering the life of the animal, if there had been no injured organ to afford the necessary conditions for the development of a septic focus. Two causes, therefore, were concerned: the injury and the septic particles which were brought to the injured part by the blood-stream; and of either it could be stated, with equal truth, that it would not have been efficient without the other. In this respect, the *bistournage* experiment admits of the same explanation as the one previously mentioned, in which a septic peritonitis was induced by the injection of a drop or two of solution of iodine into the peritoneal cavity; for, in the one case as in the other, the injury which was the immediate cause of the pathological process would have had no infectious results, unless infective particles had been present. But here the parallelism ceases; for, by a further experiment, Chauveau showed that, if the septic liquid were carefully filtered before injection, so as to deprive it of its visible particles, *bistournage* could be performed without unfavourable result. The filtrate, though obviously still contaminating, was quite innocuous. It appeared to be essential to the morbid fruitfulness of the seed sown that it should be enclosed in particles of sufficient size to lodge in the capillaries of the injured part.

[To be continued.]

#### LOCALISATION IN SPINAL DISEASE: ILLUSTRATED BY (1) A CASE OF "ATROPHIC PARALYSIS" IN AN ADULT; (2) A CASE OF CENTRAL MYELITIS; (3) A CASE OF ALCOHOLIC PARAPLEGIA.

By JAMES RUSSELL, M.D.,  
Physician to the General Hospital, Birmingham.

WE are indebted to the labours of Lockhart Clarke, of Duchenne (de Boulogne), of Charcot and his pupils, and other observers, for the knowledge that the spinal cord, though so narrow in its lateral dimensions, yet presents a special localisation in different districts, under the influence of disease, almost, if not quite, as distinct as has been observed in diseases of the brain. Several districts in the cord can be mapped out by the phenomena of disease, some of them equally distinct in their functional endowments, and some in the different periods in which they undergo development during foetal existence. Among these districts, particular interest attaches to the central grey matter, and especially to its anterior and posterior cornua; these cornua presenting a remarkable distinctness in the diseases to which they are subject, as much so as in the functions to which they are respectively subservient.

A large and important group of maladies originates in morbid changes taking place in the anterior cornua, and belongs in essentials to these cornua, the implication of neighbouring tissues constituting a secondary and subordinate process. This group has been classed by M. Charcot under the title of "myopathies spinales". In the maladies by which it is constituted, whether acute or chronic, the distinguishing characteristic is, that the transmission of sensitive impressions is not modified at all, or only in a secondary and subordinate manner. The entire stress of the disease falls upon the motor function and the nutrition of the muscles. Voluntary motion is more or less enfeebled; but what localises the paralyzing influence in the anterior horns is the muscular atrophy by which it is attended. As is well known, the atrophy in some of the diseases reaches the extent of entire destruction of the muscle affected.

My first case belongs to the acute variety of this group. It is intimately related to a well-known malady, "atrophic paralysis of infancy": a disease in which the morbid changes commence in the anterior horns of the spinal grey matter, and, according to M. Charcot, are usually restricted to one or to two of the circumscribed oval groups of large ganglionic motor cells characterising those horns. These cells form the starting-point and centre of the morbid process, and it is only in the utmost stage of alteration and in certain regions that the horn is invaded through its entire extent. (*Leçons*, 2me série, p. 181.)

\* The quantity of free oxygen in common water exposed to the atmosphere is about 0.6 per cent. per volume at ordinary temperature, that of oxygen in the blood about 0.15. The extreme smallness of the quantity of free oxygen in circulating blood is due to the presence of a body (hæmoglobin) which seizes upon the oxygen with great avidity. On the other hand, there can be no doubt that the oxygen present in the blood is sufficient for the maintenance of bacterial life; for in the experiments recently conducted under Professor Donders' supervision at Utrecht, it was found that although oxygen, as is well known, promotes the vital activity of bacteria, these organisms can live in its absence—a fact explained by supposing that they have the power of tearing it from other combinations. See Grossmann and Mayerhausen, "Ueber das Leben der Bacterien in Gasen"; *Pflüger's Archiv*, vol. xv, p. 245.

† Since delivering this lecture, I have become acquainted with a paper by P. Granitz ("Experimentelle Untersuch. über die durch Parasiten bedingten Krankheiten"; *Virchow's Archiv*, vol. lxx, p. 546), in which the author adduces several striking facts in support of the conclusion that, just as the vegetative processes of the fungi are checked whenever they are brought into competition with those of more vigorously growing organisms, so the growth of ferment organisms is restrained in presence of actively growing cells—e.g., pus-corpuscles.

‡ On the same occasion, Dr. Bastian referred to another fact of a similar nature—namely, that when by the injection of irritant liquids under the skin an inflammation of the subcutaneous tissue is produced in rabbits, the exudation liquids are found to swarm with bacteria. The explanation is, that the skin at the injured part being infiltrated with exudation, is no longer protective. Its external contaminated surface is thereby brought into relation with the subcutaneous tissues.

§ Chauveau, "Étude expérimentale sur les phénomènes de mortification et de putréfaction qui se passent dans l'organisme animal vivant"; *Bull. de l'Acad. de Médecine*, 1873, p. 520.

There is, however, a matter of interest of a different character attaching to my case; viz., that the subject of it is an adult. The malady, as its name implies, is one which has been known as belonging chiefly to early childhood. It is most frequent (Charcot) between the first and third years, is rare after the fifth year, and is quite exceptional after the tenth year. It appears, however, from a paper on the subject in *Le Progrès Médical*, 1874, No. 7, that in 1866 M. Kussmaul had formed a suspicion, correctly based on two cases of his own, that the disease may also occur at a later period of life. Afterwards M. Duchenne took up the subject. In his work *De l'Electrisation Localisée*, third edition, he has a chapter (iii, p. 437) plainly provisional, "Paralysies Spinales de l'Adulte"; and the first article, entitled "Paralysie Spinale Antérieure Aiguë de l'Adulte", is devoted to the consideration of the cases at present in question, three instances being given in illustration. Dr. Moritz Meyer, in his work on *Electricity in its Relations to Practical Medicine*, translated by Dr. Hammond, 1872, p. 229, adds to his article on "Infantile Paralysis" the remark, that a similar paralysis of the lower extremities occurs in rare cases among adults also, occasioned, he believes, either by the influence of some exanthematic action or by some other unknown cause. He proceeds to notice some particulars in which the malady, as affecting adults, differs from the ordinary phenomena presented by children. These particulars depend chiefly on the circumstances that the development of the limbs has been completed, and that the nervous functions have attained a condition of greater stability. Hence temperature is not lowered in the affected limbs as it is in those of children, and the disabling effects of the paralysis are less developed: a statement which receives illustration from the case of my patient. Dr. Meyer details two cases which occurred simultaneously in twins, in each after an attack of measles.

M. Charcot, in his second series of lectures, enlarges on the same topic, and expresses a suspicion, plainly well justified, "that cases of this kind are not unfrequently misunderstood, and that in reality they are not absolutely rare" (p. 171). He details the particulars of two cases. In an article in *Le Progrès Médical*, to which I have already referred (No. 7 and succeeding numbers, 1874), other cases are added by the authors, M.M. Bourneville and Teinturier.

Among the various cases to which I have thus alluded, there are particulars of only one *post mortem* examination. This occurred in the practice of M.M. Charcot and Gombault, in a female who died of cancer at the age of sixty-seven, having been attacked seven years before by this peculiar form of paralysis. In this case, reported in *Le Progrès Médical*, the morbid changes in the proper tissue of the cord were limited to the large motor cells of the anterior horns. The changes in these cells extended through the entire length of the cord, and were especially advanced in the lower part of the cervical region. The only other change in the cord was diminution in the size of the horizontal bundles of fibres passing from the anterior horns to the corresponding nerve-root. Certain points are remarked as distinguishing the changes in this case from the changes usual in childhood, especially that the affected horns were not lessened in size, that the white columns were not secondarily affected, and that there was no disappearance of an entire group of cells, with increase of interstitial tissue.

The general characters presented by the disease in the adult have been a close copy of those observed in childhood. Most of the cases set in with severe fever; but in one case general paralysis attacked the patient so suddenly as to be complete in half an hour, the patient thenceforward lying absolutely without power of voluntary movement for two years. In two others, also, fever seems to have been absent. Generally there appears to have been complete immunity from any interference with the cerebral functions, except that in one instance the initiatory fever was attended with delirium, and in another is described as having presented the character of an invasion of typhoid "d'une haute gravité". In two cases only was the paralysis confined to the lower extremities. In my own case, it will be seen that a still greater limitation was observed. The paralysis was attended with the usual loss of faradic contractility, and with flaccidity and atrophy of the muscles. Functional power was retained in the sphincters, and there was entire absence of any tendency to the formation of sloughs; all being characters belonging to those forms of spinal disease in which the changes are restricted to the anterior grey matter of the cord. Sensation was not impaired in any instance; but there appears to have been one particular in which the symptoms differed from those occurring in childhood; the presence, viz., in certain instances, of pain, especially seated in the vertebral region and loins, frequently radiating down the limbs. Particular mention must also be made of one case, in which a double herpes zona appeared upon the chest during the initiatory fever. This latter symptom, as well as the pains, appear to indicate a tendency in the disease of adults to transgress the limits

generally observed at an earlier period of life: a supposition favoured also by certain subjective sensations referred to the limbs, indicating irritation in the posterior cornua, with which there is every reason to associate the transmission of sensitive impressions. Finally, recovery was complete in one case only.

The ages of the patients varied between fifteen and sixty-two years. As respects the subject of causation, M. Duchenne refers to the impression of cold, especially when made whilst the subject was perspiring; and it is to be noted that this influence is prominent among the cases which I have quoted. In a case by M. Bernhardt, the element of cold was especially distinct. The patient went into the courtyard of his house without his shoes and in his night-dress, whilst in a state of profuse perspiration. On regaining his chamber and washing his hands, he found a difficulty in handling the soap. On the next evening, he had trouble in counting out money to pay for a *fiacre*: on the next day but one, he could not hold his cup, and was obliged to be fed; and, the day after, all his limbs were paralysed. He had no fever. Intense mental emotion appears also to have had some share in causing the illness in one or two instances.

CASE I.—W. B., aged 15, was a fine healthy-looking young man, free from any family history of serious disease or of rheumatism, and had enjoyed very good health. He had been subjected to a considerable amount of muscular exertion, noticed by M. Duchenne as predisposing to the disease, in having to walk a great deal. The legs of his trousers were wet through on Thursday, and were allowed to dry on him; on Friday, he complained of being cold, and on Saturday shivered and became feverish, and went to bed. At that time, he suffered from pain across the loins and down the right lower extremity. The attack lasted for two days, when he got up, but found his right leg give way. Three or four days afterwards, the pain returned, and he again went to bed; but there was no return of fever. On again getting up two or three days afterwards, the power of his right lower extremity was greatly enfeebled. The pain in the back and stiffness lasted for a fortnight longer. Seventeen weeks later, he was admitted into the Birmingham General Hospital. At his admission, the disease was found to be completely limited to the right lower extremity; all the other limbs were muscular and well developed. The patient had a light complexion, with dilated pupils. He had all the appearance of being in excellent health. The sounds of his heart were quite normal. His urine was free from albumen. Though the segments of the right lower extremity could not be employed separately, yet, by using the extremity as a whole in the manner of a crutch, the young man was able to accomplish a walk of more than three miles, though not without some muscular aching. The walk was, of course, marred by a very decided limp; the swing of the body being called in to assist the advance of the leg at each step forward. The right buttock was somewhat flattened. The right thigh was greatly atrophied; but, in the leg, the recovery of the calf-muscles occasioned the difference in girth between the two limbs to be small. During the first six weeks of residence, the right thigh lost about half an inch; the difference between the thighs on each side increasing from two inches and a half to three inches, the relative dimensions remaining afterwards unchanged. The difference between the girth of the legs increased from one-quarter to half an inch. The flexors of the thigh upon the trunk, the adductors, and the extensor muscles of the knee, though just able to effect movement in the limb, offered not the least resistance to passive motion. Extension of the thigh and flexion of the knee were both performed with considerable force. The calf-muscles possessed nearly, if not quite, their normal force, and had retained their normal nutrition; the diminution in the girth of the leg probably depending on wasting of the anterior muscles. Flexion of the toes also was performed energetically; but flexion of the foot and extension of the toes could hardly be effected at all. The muscles of the sole of the foot retained their natural amount of power and degree of nutrition. The function of sensation in all its forms was in a natural condition. There was no increase of reflex irritability. Faradic contractility was very low in both lower extremities; but there was a decided difference in favour of the left side, excepting in the muscles of the right calf, in which the contraction on each side was nearly alike. Contractility to the interrupted galvanic current was no greater than to faradism. The comparative temperature was taken twice. On one occasion, the right (diseased) limb was .6 deg. the warmer: on the second, the temperature was alike on each side. The toe-nails were unchanged.

The patient remained under observation for six months. During that period, very full trial was made of electricity by galvanism and by faradism; of shampooing the muscles; of counterirritation to the spine by means of blisters, and afterwards of the hot iron. He took iodide of potassium and tonics; but he left the hospital without having under-

gone any perceptible improvement, and not having acquired a talipes equinus, to which the preponderating action of the calf-muscles appeared to dispose him.

[To be continued.]

## ON STRICTURES OF THE INTESTINE: WITH REMARKS UPON STATISTICS AS A GUIDE TO DIAGNOSIS AND TREATMENT.\*

By SIDNEY COUPLAND, M.D., Assistant-Physician, and HENRY MORRIS, M.A., F.R.C.S., Senior Assistant-Surgeon to the Middlesex Hospital.

THE subject of intestinal obstruction has been so exhaustively treated from all sides, that it may be thought almost unnecessary to add anything to what has been already written on the question. But, during the past few years, our attention has been several times directed to the subject, owing to the comparatively large number of cases, either in the care of our colleagues or under our personal supervision, that have fallen under our observation at the Middlesex Hospital. The study of these cases has led us to carefully collate a large amount of evidence with respect to the causes and effects of that class of obstructions included under the term of "stricture" of the bowel; and the conclusions at which we have arrived seem to us worthy of some consideration, as indicating more precisely than has yet been attempted the particular lines of treatment to be adopted in such cases, so distressing in their symptoms and so fatal in their results. We wish also to call attention to the methods of diagnosis employed for detecting the seat of a stricture, when once it has been ascertained that the patient is suffering from this form of obstruction.

1. *Situation of Strictures.*—With regard to this, indeed, we have nothing novel to propound; for the ground has been already fully gone over by writers, such as Dr. Hilton Fagge in his article in *Guy's Hospital Reports* (vol. xiv, 1868)—an article which has justly become the standard of reference for all writers since it was published; Dr. Brinton, in his posthumous essay on *Intestinal Obstruction*, and others. We have, however, deemed it worth while to seek for fresh facts in this direction; and the result of our search has been, that in all respects we have been able to adduce strong confirmation of the general truth of the statements made by those authors. Our sources of inquiry have been the *post mortem* records of the Middlesex Hospital from the year 1844 to the present time (with the exception of the year 1852 and the greater part of 1851); and the *Transactions of the Pathological Society* since its formation in the year 1846. From the former source, we have collected thirty-one, and from the latter, thirty-two cases of stricture of the intestine. It is justly remarked by Dr. Fagge that the *Transactions* of a Society do not afford a correct basis for statistical inference, seeing that they include only selected cases, interesting from their rarity or some peculiarity incident to the case. This is doubtless true; but with respect to the subject under consideration, the *Transactions of the Pathological Society* are of especial value. For here, if anywhere, we should find recorded instances of stricture in unusual and rare situations, and a certain safeguard would be found against drawing too hard and fast a line in one's conclusions. It is interesting to note, therefore, that whereas the number of cases of rectal stricture to be found in these volumes is comparatively small and is below the average drawn from other sources, yet, on the other hand, only one case has been brought before that Society in which the disease giving rise to the obstruction was seated above the cæcum. Bearing in mind Dr. Fagge's reservation, we think we may fairly quote the *Pathological Transactions* in our statistical deductions. We must also add that none of the cases have been quoted twice, care having been taken to exclude from the list culled from the Society any case that had been first entered in the Middlesex Hospital records. We find, then, that out of a total of thirty-one cases of stricture of the intestines examined after death at the Middlesex Hospital, in no fewer than twenty-seven was the disease situated in the large intestine. Of the remaining four cases, in one it involved the ileo-cæcal valve; in another, the ileum at its lower end; in a third, the upper part of the ileum; and in the fourth, the jejunum. No cases of stricture of the small intestine are recorded by Dr. Brinton, by Dr. Fagge, nor by M. Duchaussoy, whose figures are quoted by Dr. Fagge; so that we may hold that instances of stricture of the ileum or above the ileum are of extreme rarity. Out of the thirty-two cases recorded in the *Pathological Transactions*, thirty-one involved the large bowel alone, and one the lower end of the ileum and the cæcum.

The case of jejunal stricture referred to occurred at the Middlesex Hospital in 1867, and is recorded as being due to cicatrisation of an ulcer. The patient was a man aged 58, who died from peritonitis consequent upon perforation above the stricture. Of the cases of ileal disease, one was that of a male aged 65, also in 1867, in whom cancer of the lower end of the ileum had determined invagination of the gut into the cæcum, and death in this case also was due to peritonitis from perforation above the stricture. The other instance occurred in 1859; it was in a female aged 42, and was a cancerous stricture of the ileum at its upper extremity, secondary to cancer of the breast. A somewhat parallel case has come under the notice of one of us in the *post mortem* room of the Middlesex Hospital during the present year. It was a case of primary epithelial cancer of the uterus, with an unusual dissemination of secondary growths, one of which had involved the lower end of the jejunum in all its coats, so as to produce an annular constriction half an inch in width. It had given rise to no symptoms during life, although the stricture was so small as to admit only of the passage of a No. 7 catheter. A mesenteric gland in connection with the affected bowel was also infiltrated. We may also refer to the two cases, out of the total number of sixty-three, in which the disease, in both cases cancer, attacked the cæcum as well as the ileum at its lower extremity. One of these was admitted into the Middlesex Hospital last October. She was only twenty-eight years of age; had been losing flesh for six months, and for three months had suffered from abdominal pain, constipation, and vomiting, the last three weeks being marked by continued enlargement of the abdomen. The lower bowel contained feces, and daily the patient passed a small quantity. There were constant attacks of severe pain, during which the coils of small intestines could be seen on the surface. Acupuncture afforded but slight relief; and death soon followed from peritonitis due to perforation of the cæcum, which, at its valve, was the seat of a luxuriant growth of epithelial cancer. The other case is recorded in the *Pathological Transactions*, vol. xii, p. 117, by Mr. G. Lawson. The patient was a woman fifty-six years of age, in whom complete obstruction had lasted for only about a week before death. The site of the ileo-cæcal valve was occupied by a dense scirrhous mass, which infiltrated also the wall of the cæcum. A similar case to the first of these is to be found in Dr. Fagge's paper (*loc. cit.*, case No. 33).

In the remaining cases, *i.e.*, in fifty-eight out of sixty-three, the seat of stricture was in the large intestine. Of the twenty-seven cases in the Middlesex Hospital, we find that in twenty-four the stricture was situated in the sigmoid flexure and rectum, there being twelve instances in each of these sites; two were in the middle portion of the transverse colon, and one was in the descending colon. It may be observed that in no case was the cæcum (alone) attacked, nor the ascending colon, nor either of the flexures of the transverse colon, the latter being generally regarded as more frequent seats of stricture than is the centre of the arch. The figures obtained from the *Pathological Transactions* accord better with generally accepted views, for there we find one case of disease of the cæcum recorded, three of the hepatic, two of the splenic flexure, and two of the middle part of the transverse colon, two of the descending colon, thirteen of the sigmoid flexure, and eight of the rectum. Thus, in round numbers, nearly three fourths of the cases of stricture involve the lower end of the intestine, the number met with in the sigmoid flexure and in the rectum being practically equal; whilst of the remaining one-fourth, the ascending colon is the rarest, and the cæcum the next rarest seat, the remainder being equally shared by the three regions of the transverse colon and the descending colon. In all but an insignificant minority of cases, the disease is seated below the cæcum; and this broad general conclusion approximates tolerably closely with the statements of the writers above named. We could point out, however, that Dr. Brinton's figures appear to us to give rather too high a range for affections of the cæcum and ascending colon.

II. *Nature of the Strictures.*—In general terms, it may be said that the majority of the strictures are malignant, and this notwithstanding the fact that few are associated with secondary infection of remote viscera. This may be explained by reason of the new growths mostly belonging to the class of epitheliomata, which are notoriously the most local of all forms of cancer, and also possibly because they lead to fatal results before the system comes to be infected. In a case under our care last year of epithelioma of the sigmoid flexure, an annular ulcer with thickened infiltrated margins, and a depressed and ulcerating base, which gave to the gut externally the appearance of having been constricted by a tight cord, the epithelial new growth infiltrated the coats of the bowel for about half an inch above and below the constriction; but there was absolutely no secondary infection in any part. A case precisely similar as to the form of local disease in the sigmoid flexure, which was in the Hospital in 1875, was asso-

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

ciated with small secondary nodules in the liver and in the cutaneous tissues of the umbilicus. We think, then, that even some cases which in past times have been recorded as instances of simple stricture may really have the same fundamental structure histologically. To the naked eye, they conform to the type of "annular ulcers", but microscopically they are composed of an exuberant growth of cylindrical epithelium in the deeper tissues of the wall of the gut, and frequently with small outpods on the serous coat. In the cæcum, this growth may attain a larger size, and, as in the case above related, may form a large cauliflower excrescence, partially filling that portion of bowel. A smaller number of cases are due to scirrhus cancer, or to colloid; whilst there remain others, which from the presence of ulceration elsewhere in the bowel and the absence of any signs of infiltrating cancer, may be attributed to the cicatrization of tubercular, dysenteric, or syphilitic ulceration; the latter, as is well known, being chiefly limited to the rectum. Analysing, as before, the sixty-three cases we have collected, we find them recorded or described as follows. Out of the thirty-two cases to be found in the *Pathological Transactions*, eighteen are recorded as cancer, eight as simple stricture, or stricture following ulceration; seven of these being in the sigmoid flexure, it is possible that some may have been of the nature of epithelioma. There is one case of stricture of the sigmoid attributed to tubercular ulceration, and in two at the same region the nature of the stricture is not alluded to. There remain two instances of supposed syphilitic stricture of the rectum, and one attributed to cicatrization of a dysenteric ulcer in the same portion of the canal. In the thirty-one cases recorded in the Middlesex Hospital register, twenty were undoubtedly cancerous; seven are described as simple strictures (but some of these, again, were in the form of "annular ulcers"), and four as "ulceration with stricture".

III. *Perforation*.—In the course of inquiry, we were struck particularly by the fact that in a large number of cases in which the obstruction was complete and where it remained until death, unrelieved by the operation of colotomy, the fatal issue was brought about by the occurrence of perforation of the gut either just above the seat of stricture or at the cæcum; and it is upon the latter complication that we desire especially to insist. Its occurrence in several cases under our own notice brought the fact forcibly before us, and has largely influenced us in advising a definite line of procedure. The occurrence of inflammation and ulceration of the intestines from simple accumulation of their contents is notorious. The history of ordinary typhlitis is an illustration of this; and, not to mention the, unhappily, too frequent instances of perforation of the vermiform appendix from impacted feces, we could instance several cases in which the cæcum itself and other portions of the canal have suffered extremely from a like cause, even to the extent of perforation. In the class of cases we are particularly considering, the cæcum is usually the point to suffer most severely; but here again we proclaim no novelty;\* we only affirm that the fact has not perhaps received sufficient attention. Dr. Hilton Fagge refers to it in his paper—it was met with in four of his cases; and he adds further that Dr. Wilks "had seen, in his private practice, a case of stricture of the colon, which (although it never caused total obstruction) gave rise to accumulation in the cæcum, to inflammation and perforation of this part of the bowel, and consequently to the death of the patient". If we turn to our own experience, one of the most striking instances we have seen was in a female patient thirty-five years of age, who was admitted into the Middlesex Hospital under the care of Dr. Greenhow on November 25th, 1873. She had been losing flesh for the past two years, and during the same time, had been subject to hypogastric pain and more or less constipation, which had become pronounced only for twelve days. She had travelled up from Wales to enter a London hospital; and, on admission, she was evidently dying from peritonitis. She lived but six hours; and after death the obstruction was found to be due to cancer of the body of the uterus invading the rectum; all the intestines were enormously distended with fecal matter, and fecal matter had escaped in large quantity into the peritoneal cavity. This extravasation was due to a perforation of the cæcum, the walls of which were extensively ulcerated. In 1874, a man, thirty-two years of age, with cancer of the rectum, also died from peritonitis due to perforation of the cæcum, there being no ulceration present in any other part of the greatly distended bowels. In 1876, two cases which came under our notice of annular stricture of

the sigmoid, both in females, also terminated in this manner. In one, the cæcum was opened shortly before death; and in the other, the ascending colon; but in both, the operation was done too late to prevent the perforation of the cæcum, which, in one case at least, must have been established before the operation. Lastly, in the remarkable case of epithelial cancer of the ileo-cæcal valve already referred to, which allowed the entrance of fecal matter into, but partially hindered its exit from the cæcum, there was extreme disorganisation of the walls of this *cul-de-sac*.

We need not here dwell upon these cases, but they all illustrate forcibly the fact of cæcal ulceration in cases of stricture even so far removed from the cæcum as the lower end of the rectum. The reason why the cæcum suffers in this way is not far to seek. In cases of simple accumulation, it is generally the chief part to be involved; and in cases of accumulation from organic stricture beyond, the same causes operate with increased force. These are, first, the shape of the cæcum, a mere *cul-de-sac*, above and on the inner side of which the ileum opens at a right angle. It thus acts as a kind of reservoir, where, in cases of obstruction in the course of the large bowel beyond, it serves as it were for the meeting of the two currents, that, namely, setting downwards from the ileum, and that regurgitated backwards from the seat of obstruction. Its dependent position is a second factor favourable to accumulation within it. More effectual still is its fixity, placed as it is between the abdominal wall in front and the iliacus muscle behind, and only partially invested by peritoneum, except in rare cases. Hence its power of independent movement is very slight; and that will be lost with the increasing distension. Contrast this with the transverse colon, which being, as a rule, more free, is enabled, so long as its muscular walls retain their tonicity, to empty itself. Further, to all this must be added the constant chafing of the distended gut by the action of the abdominal and iliacus muscles between which it is placed.

We are unable to give any accurate statistical details in support of our assertion of the frequency with which this cæcal ulceration occurs, owing simply to the fact that in a considerable number of cases the state of the intestinal mucous membrane above the stricture has not been put on record, or, if mentioned at all, the description is usually limited to the few inches of bowel in the neighbourhood of the stricture, except in those cases which have proved fatal from perforation. Eliminating twenty-six cases in which the state of the mucous membrane is not described, we find that ulceration occurred in the cæcum, or in its vicinity, and far removed from the seat of stricture, in fourteen out of thirty-one, a proportion which, judging from our own limited experience, is considerably within the mark.

IV. *Treatment*.—We pass now to the question of treatment, which, we think, should be based upon the knowledge of these facts. Obviously, those cases of rectal cancer must be set aside in which the diagnosis by means of physical examination is easy, or in which the nature of the case has been made out long prior to the supervention of total obstruction. Of course, in such cases, the only rational procedure is that universally pursued by surgeons, viz., left colotomy; and all, in such cases, recognise the futility of delay and the long-lasting relief, for months or even for years, frequently obtained by that operation. But in all other cases, where the history is one of chronic obstruction, where the age of the patient favours the view of cancer, where, in fine, it is probable that a stricture of the bowel exists, then, without wasting time over repeated injections, administering powerful and harmful purgatives, we think that recourse should speedily be had to colotomy in the right loin. We advise this operation, because in a certain proportion of cases (about one-fourth) the stricture is higher than the sigmoid flexure; because in all these cases, whether the obstructing cause be far from or near to the cæcum, there is undue strain thrown upon that portion of the canal; and because the only chance of a favourable issue (in so far as an operation for relief of symptoms can be said to have a favourable result) obviously lies in giving prompt and early relief to the cæcum thus overstrained. It must be borne in mind that cases have occurred in which, the symptoms pointing to the disease in the sigmoid flexure, the descending colon has been opened and found to be empty, owing to the obstruction being situated in the course of the transverse colon or in one of its flexures. Had the operation of right colotomy been performed, not only would it have been above the seat of stricture, but it would also have at once unloaded the distended cæcum. The danger of delaying this operation cannot be too strictly insisted upon. Unfortunately, in the majority of cases, the surgeon is not called until the obstruction has been already complete for some time, and the cæcum has suffered in proportion. A case of stricture under our care last year, affords an illustration of this. The patient, a woman fifty years of age, was admitted into the

\* Seventeen years ago, it was alluded to as a well known fact by Dr. J. C. Messer, apropos of a case of stricture of the rectum, complicated by perforation of the cæcum. He says: "The existence of ulceration of the cæcum in such cases has been remarked, and was present in this instance. The explanation of this circumstance would appear to be, that the walls of the cæcum are more easily affected by the distending pressure of accumulating feces, which ultimately results in ulceration." *Pathological Transactions*, vol. xi, p. 110.

Hospital on October 10th, 1876, with a history of complete constipation of twelve days' standing, unrelieved by purgative medicines. There was great distension of the abdomen to about an equal extent on both sides, perhaps some slight fulness in the right iliac region. There was no vomiting. A long tube was passed *per anum* to the extent of twelve inches; warm water injected into it could not be heard on auscultation to find its way into the cæcum, and was speedily returned, without the passage of either feces or flatus. When the patient was under the influence of chloroform, the hand was introduced into the lower bowel, without meeting with any obstruction except that which appeared to be a fold of mucous membrane. Right colotomy was performed about six hours after admission, and was followed by marked relief to the distressing symptoms of distension, etc., but the patient sank from peritonitis, dying thirty-six hours after the operation. The peritonitis—which must have been present on admission—was due to ulceration of the coats of the cæcum, leading to extravasation of its contents into the peritoneal cavity. The stricture was confined to the sigmoid flexure. In the twenty-third volume of the *Pathological Transactions* (p. 119), Dr. Bristowe records a case of colloid cancer of the splenic flexure in a young man twenty-three years of age, in which for some days injections appeared to give relief, and in which, at length, the operation of right colotomy was entertained. The patient died, however, a few hours before the morning fixed for the operation, and ten days after his admission into the hospital. There was perforation of the ileum close to the cæcum, the lower end of the small bowel being extensively ulcerated.

But we would go further than this. The operation of right colotomy may have failed in its main object, owing to the disease being situated in the cæcum or small intestine, for so difficult is the diagnosis in cases where the abdomen is uniformly distended that to ascertain the precise seat of a stricture is well-nigh impossible. The ascending colon may then be found collapsed and empty. In such a case, the wound in the loin should be stitched up, and relief afforded to the distended bowels by the operation of enterotomy, or the small bowel may be opened at the loin if thought desirable. The intolerable distress from fecal and gaseous accumulation endured by the patient is too great to be let pass, without an effort on the part of the surgeon to remove its cause. Possibly he cannot hope to do much more than ease the path to death; but surely that is some gain. The desirability of performing this operation to give relief to over-distended intestines was insisted on by Trousseau (*Lectures on Clinical Medicine*, New Syd. Soc. Ed., vol. iv, p. 205), who, in his lecture on intestinal obstruction, gives directions as to the performance of enterotomy. He relates, also, four cases in which recourse was had to the operation at his suggestion, and as a final attempt, to relieve symptoms of obstruction. In two of these cases, the patients recovered, both being, probably, cases of volvulus or internal strangulation of the small intestines. In the *Medico-Chirurgical Transactions* for 1872 (vol. iv, p. 267) Mr. McCarthy relates a case of cancer of the stomach involving the splenic flexure, in which, on the advice of Mr. Maunder, he performed enterotomy in the right inguinal region, and with perfect success. The patient died from the cancerous disease and fatty degeneration of the heart, seven weeks after the operation. The operation has also been performed by Mr. Wagstaffe (*St. Thomas's Hospital Reports*, 1873, p. 181), for the relief of great distension and sickness from obstruction due to a pelvic tumour; and with such success that the patient was alive four years after the operation; and by Mr. Maunder (*Clinical Society's Transactions*, ix, p. 102), in a case of suspected stricture at the lower part of the ileum. The patient, who was sixty-eight years of age, lived for some months after the operation. It has also been performed by Mr. Bryant with a successful result. For ourselves, we may say that to us it seems that in all such cases, where the distension of the intestines is a source of suffering, as well as of danger, the operation of enterotomy is as imperatively called for as is that of puncture of the bladder in cases of overdistension of that viscus from impermeable stricture, and notwithstanding that fatal disease of the kidney may be already established. We hold that a free opening into the bowel is at once more effectual and safer than the method of acupuncture, which has been frequently adopted of late years. It is true that many may hold with Trousseau that puncture is not dangerous; but in a recent discussion at the Clinical Society of London, there appeared to be a pretty general consensus of opinion that acupuncture of the bowels was in many cases attended with considerable risk. Mr. Bryant said that in two cases in which he had practised it, fecal extravasation resulted; and Dr. Silver, although urging the necessity of the procedure for the relief of overdistension, admitted that in one case, fecal extravasation had occurred. In Dr. Bristowe's case of stricture at the splenic flexure, fatal from ulceration of the ileum, acupuncture was practised. It produced temporary relief, but seemed to

determine the fatal perforation of the bowel. Certainly, this happened in the case of ileo-cæcal cancer under our care last year; for there numerous punctures were made into the various distended coils of small intestine, and were followed by a considerable escape of flatus, with slight diminution of the girth of the patient. The operation was also, however, followed by increased violence in the peristalsis of the small intestines, with a proportionately great increase in pain, and the patient died from peritonitis due to perforation of the cæcum. Neither in this, nor in Dr. Bristowe's case, was there evidence of there having been any extravasation at the seats of puncture. There is more risk of such extravasation where the muscular coat has lost its tone and the walls are thinned by distension or spoiled by inflammation. This was well seen in a case of internal strangulation, under the care of Mr. Hulke, at the Middlesex Hospital in 1872, and recorded by him in the *Medical Times and Gazette* (1872, vol. ii, p. 463). In this case, acupuncture was resorted to for the purpose of replacing coils of small intestine which had been drawn out of the abdomen in the search for the constricting band. The puncture allowing not only of the escape of flatus but also of the oozing of feces, Mr. Hulke laid the bowel open at the spot and made an artificial anus in the small intestine. In Dr. Bristowe's and our own cases, the puncture appeared to be the exciting cause of the perforation of the ulcers produced by the fecal accumulation, probably by exciting a more ready contraction of the small intestines, owing to the displacement of their contents. Had a free opening been made, however, it is probable that by thus allowing a vent for the escape of the feces, the cæcum or the lower end of the ileum would not have been exposed to the additional strain caused by the increased peristaltic action. We have three times witnessed the great relief experienced by the operation of enterotomy in these cases; once in the case of Mr. Hulke, just referred to, and again last year in a patient of Dr. Henry Thompson (a case of sigmoid stricture), where the cæcum, already far advanced in ulceration, was laid open in the operation by one of us, and thus exit was given to an enormous quantity of feces. In both cases—although the patient only survived for a few hours—the relief obtained was very marked. The third case was one of obstruction from intussusception, where twenty-four inches of ileum were removed, and a double artificial anus made. The patient lived twenty hours after the operation, and for many hours was made easy and even cheerful by it (*Transactions of the Pathological Society*, vol. xxviii, p. 131).

v. *Diagnosis*.—What we have to say upon the subject of diagnosis may be summed up in a very few words. We must confess, with Dr. Fagge, that so far as regards the methods employed for the accurate diagnosis of the seat of a stricture of the intestine, it is often impossible to be sure whether the disease is situated in the small or large bowel; and if it be in the large intestine, its precise situation there is extremely difficult to determine. All the rules based upon the symptoms of the disease have been at different times found wanting; and much the same statement may be made in truth with regard to such aids to diagnosis as are afforded by the amount of fluid that may be injected into the canal, by auscultation over various parts of its course during the injection and even by the passage of the long tube. In every case where digital examination has proved negative, it might be worth while to adopt the method first practised in this country by Mr. Maunder, largely employed by Professor Simon of Heidelberg, and advocated by Mr. Walsbam of St. Bartholomew's Hospital; that, namely, of the introduction of the whole hand into the rectum. This method was employed in our case (above referred to) of stricture of the sigmoid, but, owing to the folds of the canal, the stricture was not reached; and it was well that it was not, for at the necropsy subsequently, the bowel at the seat of stricture gave way on the slightest traction. Mr. Walsbam also had failed in detecting a stricture of the sigmoid flexure by this means; so that, valuable as the method may be, it cannot be fully relied on, and, moreover, it should be practised with the greatest caution.

But, after all, from what has gone before, it will be seen that, in our opinion, the precise determination of the seat of stricture is not of primary importance. In determining this seat, we are thrown back upon statistics: a knowledge of these will be a valuable guide, and they should be taken into prominent account when forming a diagnosis. We know that three-fourths of the cases of stricture involve the rectum and the sigmoid flexure; and we know that, of the remaining one-fourth, a very small proportion are seated above the ileo-cæcal valve. Nor if we have arrived only at so imperfect a diagnosis as one based upon mere numerical averages, is our line of treatment at all the less secure. For we know, also, that the chief part of the passage to suffer from the effects of stricture of the large bowel is the cæcum; and we know that, if the ascending colon be opened, in 90 per cent. of these cases the opening will be above the seat of

stricture, and will also give relief to the overdistended cæcum; whilst, as for the remainder—that is, those cases in which colotomy fails in its object—enterotomy should be performed and relief thus afforded, although it may be with but a very imperfect conception as to the exact locality of the source of obstruction.

[Since this paper was written, we have been informed by Mr. Maunder that, after hearing the views expressed therein respecting right colotomy before gastro-enterotomy, he was prepared to act on the suggestion in a case under his care; but the necessity for enterotomy did not arise, as he found the right colon distended.]

## THE SILK LIGATURE AS A METHOD OF SECURING THE OVARIAN PEDICLE:

ITS ADVANTAGES AND DISADVANTAGES, WITH BRIEF NOTES OF ITS RESULTS IN THIRTY-EIGHT CASES.

By J. KNOWSLEY THORNTON, M.B.,

Surgeon to the Samaritan Free Hospital for Women and Children.

SOON after commencing to perform ovariectomy, I determined to give the silk ligature a fair trial in a series of consecutive cases. It seemed to me worthy of such a trial, because of its universal applicability, its cleanness and neatness, both at the time of operation and in the after-progress of the case, and because it yielded such good results in the hands of those who only used it in cases in which it alone was applicable.

With the works of Spencer Wells and Peaslee in our hands, in which the whole question of its use is ably discussed, a paper on this subject may seem unnecessary. It differs, however, from the treatment of the subject in either of the works named, inasmuch as it deals only with one of the methods of using the silk ligature which they describe, viz., that in which the ligature or ligatures are made to transfix the pedicle, both ends being then cut off close to the knot and returned with the pedicle-stump free into the peritoneal cavity. I should hope that the old plan of leaving one end of the ligature hanging out at the lower angle of the wound has for ever passed away. It has no advantages to recommend it, and at least two serious disadvantages to contraindicate it. It necessitates the cutting off of the distal end of the stump by ulceration, and, during this slow process, it keeps open a moist highway for the causes of irritation and putrefaction to travel by from the exterior of the wound to its deepest recesses; to the very parts, in fact, which we wish to heal as quickly as possible.

Before proceeding to discuss the details of its application and the difficulties and dangers to be encountered, I will sketch briefly the various methods by which the healing process is accomplished and the ligature disposed of.

It always seemed to me probable that, though the tissues included in the ligature were tightly enough constricted to prevent hæmorrhage, they were not usually so grasped as to completely destroy the nutrition of the distal end of the stump. The following observation confirms the correctness of this view. In one of my cases, I tied a large piece of omentum adhering to the cyst in two places and divided it between the ligatures, thus leaving a stump on the outside of the tumour very like that of the ovarian pedicle. I afterwards injected the cyst with Beale's Prussian blue fluid, and, when the injection was complete, noticed that the distal end of this stump was blue, though not so blue as the proximal part, and there was no appreciable escape of the fluid from its cut surface. Microscopic examination showed that the injection had passed into the minute capillaries, but not into the larger vessels, except where it had passed into them by the anastomoses beyond the ligature.

If the injection would so pass, the blood would also pass; and in this way the vitality of the part would be at any rate partially sustained until the other processes by which the distal end of the stump is nourished had time to be completed.

The five following conditions of the stump after ligature I have myself observed in the dead or living subject. I do not claim any novelty for the observations, but, so far as I am aware, they have not as yet been all recorded side by side.

1. The ligature is buried in the peritoneal coat of the pedicle, the portions on the opposite sides adhere, and vascular connections are thus rapidly established. Cells penetrate between the fibres of the silk and break up the ligature, which is absorbed and disappears. The finer the silk used, and the softer the pedicle, the more likely is this to happen.

2. Lymph is thrown out over the ligature and cut end of the stump; in this new vessels are formed, and the same result is obtained, but more slowly.

3. The stump adheres to some neighbouring peritoneal surface, and from that new vessels pass into it, through which its nourishment is obtained.

It will at once be seen how the passage of some nutriment through the capillaries in the constricted portion must aid either of these processes, and we must also remember that the pedicle is surrounded by the nutritive fluid naturally present between the peritoneal surfaces, and probably always somewhat increased when repair is going on.

The first two of these methods are the most favourable, and are those which we must aim at securing. As a result of either of them, the stump may be in a few months merely represented by a little button of smooth tissue at the site of the pedicle. Such a result I had an opportunity of seeing when assisting my colleague Dr. Bantock at an exploratory operation a few months after ovariectomy. The exploration revealed the above condition of the pedicle, which was not adherent to any neighbouring surface, and was also quite free from the malignant disease of the peritoneum which had caused reaccumulation of fluid. How often such a result is obtained it is of course impossible to say, but I think we may fairly suppose it to have occurred when there is no symptom of any irritation about the pedicle, or at any rate in the majority of such cases (*vide* Cases I, VII, VIII, X, XI, XIV, XV, XVII, XVIII, XXII, etc.). When the stump adheres to some neighbouring peritoneal surface, most commonly some part of the intestine, because they are generally in contact with it, we are by no means likely to get such a good result. We may have no sign of mischief for some time, usually not till after the bowels have been moved. Sometimes, however, some intestinal irritation shows itself much earlier, especially if there be trouble with flatulent distension; indeed, the latter is often a sign of the irritation. When symptoms follow the first action of the bowels, they usually appear from the tenth to the fourteenth day. There is usually some rise of pulse and temperature; this may be considerable, and is, I think, proportionate to the extent of adhesion which has been disturbed. There is often depression of spirits, pain about the pedicle, and sometimes hardness may be detected in the iliac fossa, or by vaginal or rectal examination. All the symptoms may gradually subside, or they may persist for some time with obstruction to the passage of the flatus and feces or with troublesome diarrhoea and tenesmus. In the former case, fatal obstruction may result; in the latter, the case will end in discharge of pus by rectum or vagina, and all will go well. In the cases given below, examples of each of these results may be found except that of fatal intestinal obstruction.

IV. Fatal hæmorrhage may follow the use of the ligature, and one such case (XX) may be found below; and the same accident has been reported to me by several surgeons as having occurred in their practice. This most formidable accident is due to the escape of one or more of the large veins, which are common at the outer edge of the pedicle (pampiniform plexus), from the external loop of the ligature. It requires great care and some experience to avoid it, when treating a very broad and short pedicle.

V. The ligatures may remain uncovered around the pedicle in cases where diffuse peritonitis with effusion of serum or rapid septicæmia follows the operation; and if the patient survive only a few hours, they will be found just as they were when applied; or if she survive for a longer period, they may be found somewhat loose, with an ulcerated groove round the pedicle, the distal end being in a sloughing condition.

I do not think the fatal result is much influenced by the ligature in this last class of cases, though it is possible that it may become early soaked with the products of putrefaction and be a constant source for their propagation; whereas the tissues might have been able to dispose of the putrid or irritative matter had no such absorbent material been present to hold it. Excluding these cases from our consideration, we still have a formidable array of dangers to consider; but, fortunately, experience teaches us that the favourable terminations are the most common after the use of the ligature, as the cases here given will show. There being only five fatal cases out of a total of thirty-eight, and only one of these fairly to be attributed to the ligature; two of the others (Cases II and XIX), being hopeless under any treatment, and the other two sufficiently serious to render it impossible to attribute the fatal result to the ligature, at any rate with certainty.

I will now endeavour to point out certain precautions to be adopted in using the ligature, which will, I think, ensure for it results even more favourable than my own have been up to the present time.

First, as to the material. It should be the pure Chinese silk, without any admixture of cotton. The hemp ligature still finds some advocates, but it has, so far as I can see, no advantages, and the great disadvantage of being a vegetable instead of an animal tissue, and it is slippery and cutting to the fingers when wet. One advantage claimed for it is that it shrinks after tying, and hence is a security against

hæmorrhage. From experiments I have made with it, I do not believe it shrinks at all after it is once thoroughly wet, and this it always is before it is tied; and, if it did so shrink, I should not consider it an advantage in view of what I have already said as to the partial circulation through the constricted portion. The silk, if properly tied, never fails to sufficiently constrict. As to the method of applying the silk, I believe it to be important that the two ligatures should interlock when tied, so as to form a figure of eight, otherwise they may pull apart at the point of puncture and hæmorrhage may result. In a thin pedicle, it is easy to avoid puncturing a vessel, and the interlocking of the ligatures is a matter of less consequence; but, in a thick one, it is often impossible to see and avoid every vessel of sufficient size to be dangerous if punctured. If more than one transfixion be required, the ligatures should all interlock so as to form a chain. This has one disadvantage, tending, in a broad short pedicle, to cause a drag upon the outer loop of the ligature-chain, and hence to increase the risk of hæmorrhage from slipping of some of the large veins to which I have referred. The weight of the uterus and other ovary, aided perhaps by the contractile nature of the tissue of the broad ligament, increases this risk. It is well, therefore, in every case, to examine the pedicle-stump carefully just before closing the incision; and, if any sign of hæmorrhage or slipping be found, to apply a fine silk or catgut ligature by transfixion on the proximal side of the other ligatures, this last ligature to include the veins already referred to. I always adopt this plan now, using either fine silk or catgut wherever the outer edge of the broad ligament feels tight as one passes the fingers along it from the pelvic brim to the edge of the pedicle. In all the earlier cases, I employed very thick silk, and seldom more than a single transfixion, with an accessory ligature if necessary. Thinking this thick silk might be the chief cause of the trouble with the pedicle, I tried a medium thickness, tying the pedicle in smaller pieces and with more transfixions. I found the results satisfactory, and I now use the finest silk that will bear the necessary strain in tying.

Since performing ovariectomy antiseptically, I have, whenever it was possible, sewn the posterior peritoneal cut surface of the pedicle over on to the anterior surface of the broad ligament with fine silk or catgut with a view of covering over the raw surface, and at the same time placing it in immediate contact with a peritoneal surface, from which it might receive its blood-supply quickly. This method has also the great advantage of carrying the stump over to the anterior surface of the broad ligament, and so away from the risk of adhering to the intestines. I am not prepared to advocate this proceeding, however, unless the operation be performed antiseptically, because it has the disadvantage of opening up the cellular tissue of the broad ligament, and it is very probable in some of the cases small vessels are also transfixed in their continuity. In cases where the pedicle is very broad, thick, and short, this sort of flap operation would not be possible; but I think a suggestion made to me by Mr. Lister would answer well in such cases, viz., to unite the cut peritoneal edges of the stump with catgut sutures, placing a few strands of catgut between the sutures to drain, and prevent any possible risk from accumulation of serous fluid and tension.

I am aware that the catgut ligature has been successfully used instead of silk for securing the pedicle, but the results with the silk are so good that I shall not change it for catgut, at any rate, until one can be more certain of always getting a good sample of the catgut. As at present sold, it is too uncertain in its quality.

CASE I.—Both ovaries removed; clamp on left pedicle; right one transfixed and tied in two parts with strong silk, one ligature being made to encircle the whole again. Recovery perfect; no sign of mischief from the stump or ligatures.

CASE II (D).—Right ovary removed; pedicle trans-fixed and tied in two parts and returned. Case of gangrene of cyst after tapping during pregnancy. Died in sixteen hours.

To save repetitions, I may state that in every case, when no special reference to method or nature is made, the strong silk was used, the ends in all cases being cut off close to the knots, transfixion was employed, and the pedicle always dropped free into the peritoneum.

CASE III (D).—Both ovaries; very complicated case; extensive uterine, vesical, intestinal, and omental adhesions; several transfixions and many ligatures used. Wound continued to discharge for months after the operation, and several of the ligatures came away. Now in good health.

CASE IV.—Left ovary; ligatured as in Case I. On sixteenth day, irritability of bowels, passing off in a few days. Went home well on twenty-third day.

CASE V (D).—Left ovary; an enormous solid dermoid tumour;

strong silk soaked in carbolic oil; right ovary; fine silk also, soaked in carbolic oil. Died on fifth day; congestion of the brain. There was nothing to show that the ligatures influenced the result.

CASE VI.—Right ovary. On fifteenth day, I noted "Bowels do not act very well, and patient is evidently suffering from the irritation which ligatured cases so often have twelve or fourteen days after operation". Went home well on eighteenth day.

CASE VII.—Both ovaries; each two ligatures. No sign of irritation. CASE VIII.—Left ovary; combination of enucleation and ligatures; three medium silk ligatures used. No trouble of any kind. Left hospital on twenty-first day.

CASE IX.—Right ovary; similar to last, but thick silk used. Died on fifth day. (?) Pyæmia.

CASE X.—Left ovary. No trouble. Went home on twenty-second day.

CASE XI.—Enormous dermoid tumour of right ovary, with very extensive adhesions; smaller one of left ovary; two ligatures on each pedicle. Slow recovery, but no symptom referable to ligatures.

CASE XII.—Both ovaries; two ligatures on each; abscess in left iliac fossa discharged by abdominal wound. Bowels were very irritable for a week from fifteenth day onwards. Slow but perfect recovery.

CASE XIII.—Right ovary; two ligatures; many finer ones on adhesions. Much trouble with suppuration in abdomen. Very slow recovery.

CASE XIV.—Both ovaries; right, strong silk; left, medium silk; each two ligatures. Rapid recovery; temperature never rose above 99.6 deg.

CASE XV.—Left ovary; two ligatures. Good recovery.

CASE XVI (D).—Right ovary; combination of enucleation and ligatures; four transfixions with medium silk; tumour peeled off a large fibroid uterus; abscess in right iliac region discharged by wound. Phlegmasia dolens first in left leg, then in right. Recovery perfect; went home on fifty-fifth day.

CASE XVII.—Left ovary; two ligatures. No after-trouble. Up in a fortnight.

CASE XVIII.—Right ovary; two ligatures. No after-trouble.

CASE XIX (D).—Inflamed cyst united to both ovaries and everything it was in contact with; numerous ligatures. Hopeless case. Died in seventy-two hours from suppression of urine.

CASE XX.—Right ovary; two ligatures; portions of pedicle slipped from outer one, and serious hæmorrhage occurred. I did not discover it for three hours, then found bleeding-point and secured it; but she never rallied. Died in nine hours.

CASE XXI.—Left ovary; several transfixions; laced ligature. Bowels acted on ninth day, and again on twelfth. On fourteenth day, great rise of temperature and pulse, followed by diarrhoea; pus in the evacuations. Not right again till twenty-first day.

CASE XXII.—Both ovaries; right, two ligatures; left, four; laced. No after-trouble. Went home on twentieth day.

CASE XXIII.—Left ovary; several ligatures, laced; firm pelvic adhesion also transfixed and tied in two halves. No after-trouble. Went home on twenty-first day after operation.

CASE XXIV (D).—Right ovary; laced with strong silk; several transfixions. No after-trouble. Went home on twenty-seventh day.

CASE XXV (D).—Left ovary; four ligatures. No after-trouble. Went home on twentieth day.

CASE XXVI.—Left ovary; two ligatures; many others on very extensive vascular adhesions. Nearly died from sickness, commencing on eighth day; afterwards had offensive diarrhoea. Went home well on twenty-first day.

CASE XXVII (D).—Both ovaries; three ligatures on each pedicle. A great deal of pain and trouble afterwards. Went home on twenty-second day.

CASE XXVIII (D).—Both ovaries united into one large universally adherent tumour; two ligatures on each pedicle; many on adhesion. No after-trouble. Went home on twenty-third day.

CASE XXIX.—Both ovaries; three to four laced ligatures on each. Much trouble with bowels, commencing on twelfth day; pain, depression, high temperature; pus in evacuations. Went home on twenty-second day.

CASE XXX (D).—Both ovaries; several ligatures on each. Chronic pyæmic condition followed operation; bowels very troublesome. Went home well on twenty-seventh day.

CASE XXXI (D).—Right ovary; three ligatures. No trouble referable to pedicle. Went out of hospital on eighteenth day.

CASE XXXII.—Left ovary; antiseptic operation; four thick silk ligatures soaked in carbolic oil. Much trouble with bowels from twelfth day; ended in abscess discharged *per rectum*. Went out on twenty-fifth day.

CASE XXXIII.—Right ovary; antiseptic method; two ligatures soaked in carbolised oil. Much trouble with bowels commencing before they had acted, afterwards threatening complete obstruction; gradually passed off; and patient went out on twenty-fourth day.

CASE XXXIV (D).—Left ovary; antiseptic method; two strong silk ligatures soaked in watery solution of carbolic acid (1 in 20); three fine ones in carbolised oil. No after-trouble. Went home on nineteenth day.

CASE XXXV.—Right ovary; antiseptic method; two strong silk ligatures soaked in watery solution of carbolic acid (1 in 20); partial flap operation mentioned above. No after-trouble. Bowels open on eighth day. Patient up on couch on eleventh day.

CASE XXXVI.—Right ovary; antiseptic method; five medium silk ligatures soaked in watery solution of carbolic acid; partial flap operation. No after-trouble. Went out well on seventeenth day.

CASE XXXVII.—Left ovary; antiseptic method; four medium silk ligatures (carbolised). No after-trouble.

CASE XXXVIII.—Left ovary; antiseptic method: two fine silk ligatures (carbolised); partial flap operation. Went out quite well on nineteenth day.

In the above cases, I have placed the letter (D) to those in which drainage was employed, as it is often an important element of success in cases treated by ligature. Other details I have purposely left out, as they are such as are common to cases treated by any method, and therefore do not affect the special question of ligature.

I may mention that I have followed the history of all my cases since they left my care, and in no case have I heard of any after-mischief from the ligature. All upon whom I have operated, who recovered, were still in good health a few weeks ago.

## ON THE THERAPEUTIC USE OF IODOFORM.

By BERKELEY HILL, M.B., F.R.C.S.,

Professor of Clinical Surgery in University College; Surgeon to University College Hospital, and to the Lock Hospital.

LOCALLY, iodoform, as a dry powder, brushed lightly over the surface with a moistened camel-hair pencil, has been for three years my almost invariable treatment of venereal sores, especially the local chancre. During the last few months, I have often substituted for the dry powder an ethereal solution (one part of iodoform in six or eight of ether). The sore is touched or dabbed with a pencil dipped in the ethereal solution, according to its size and depth, lightly or copiously. The ether quickly evaporates, leaving a thin pellicle of iodoform, that as effectually stays the spread and produces healing of chancres as does the more copiously applied dry powder. Thus the surface is covered more exactly, and the disagreeable smell of the iodoform is too faint to attract attention. The sore is well washed with water and dried before the iodoform is applied, and the surface is lastly protected by a bit of dry lint. When the secretion is abundant, the dressing must be renewed twice daily, but in three or four days the amount of discharge becomes so scant that one dressing *per diem* suffices.

In this way, venereal sores heal quickly. Pain subsides at once; the sore is well in a week or ten days, and the chances of consecutive inoculation or bubo are greatly lessened. In a very few cases, the application of iodoform gives momentary smarting, which is very bearable; even the ethereal solution does not hurt, and usually the patient declares the application to be quite painless. I avoid using iodoform on inflamed sores, or on simple granulating wounds; but indolent non-specific ulcers are rapidly improved by iodoform locally applied.

Lately, I have given iodoform internally with great benefit. It acts more rapidly than potassic or other iodides, and, judging from experience thus far, is as readily borne as are those salts. I have given it in one-and-a-half-grain doses as a pill with extract of gentian. Three pills are given each day, increasing gradually till eight or ten pills are taken in twenty-four hours.

I have used it with excellent effect in cases of obstinate syphilitic ulceration of the tongue, where the dorsum is covered with rugged thickened epithelium, which is constantly splitting into deep fissures, and thus causing continual severe pain to the patient. This affection is often quite insensible to mercury, alkaline iodides, or arsenic—the remedies usually beneficial. In three of these obstinate cases, where I had been treating the patients at intervals for years with the remedies just mentioned with little lasting benefit, iodoform-pills have acted like a charm. Pain, immediately lessened, in two or three days ceased wholly; and the fissures healed rapidly, while the tongue soon shrank to its natural size. How long the relief will endure, time alone will show; but any interval of only apparent cure of this very painful affection is a great blessing to the sufferer, and time is given for the exhibi-

tion of mercury if required. In December last, I had under my care in University College Hospital a patient with ulcerated and protruding gumma of the left testis, non-ulcerating gumma of the right testis, and ulcerating gummata of the skin over the upper end of the right tibia, with other syphilitic affections. Iodoform was administered in pills, and water-dressing applied to the ulcers. Rapid healing and subsidence of the swellings took place, notwithstanding that, when the dose of eight pills *per diem* had been reached and administered for three days, an outbreak of pyrexia, coryza, and iodic acne rendered it necessary to drop the drug completely for a short time. In three weeks, the patient left the hospital almost healed, and continued his treatment as an out-patient. Again, a lady who has during the last two years consulted me occasionally for intensely agonising pain in the head caused by syphilitic pericranial and cranial disease, for which a customary dose was thirty grains of sodium iodide three times daily, was at once relieved of pain by the iodoform pill taken three times daily, though, on the third day, nausea became too urgent to allow the iodoform to be continued in that quantity; it was at first diminished till pain ceased, and then discontinued altogether. This small experience has satisfied me that in iodoform we have a very useful addition to our store of weapons for fighting syphilis. Further observation will enable us to apply it more exactly and when most suitable.

## THERAPEUTIC MEMORANDA.

### CHLORAL-HYDRATE IN DELIRIUM TREMENS.

A SHORT time ago, I was almost despairing of a case of delirium tremens. The man was most violent, and in a fearful state of excitement; and the remedies adopted appeared only to increase his activity and make him more and more unmanageable. The treatment had been Battley's solution in half-drachm doses; afterwards pure solution of the hydrochlorate of morphia by subcutaneous injection, as much as one grain repeated every two hours. There was no vomiting of the mixtures given on any occasion; these being, in addition to the liquor opii sedativus just mentioned, half-drachm doses of tincture of digitalis given every two hours, etc. After two or three days of the above treatment, and no improvement taking place, I determined to try the chloral-hydrate. Accordingly, at 5.10 A.M. I gave him half a drachm (thirty grains), and the same quantity at 5.40. At 6 o'clock, he had a subcutaneous injection of half a grain of morphia. At 6.10, forty grains of chloral were given; at 6.25, two-thirds of a grain of morphia were injected; and at 6.45 he was asleep. The man slept for eight hours, and awoke without headache or other unpleasant feeling except great thirst. He was now supplied with good nourishing food (beef-tea, etc.), and he was out walking next day. The quantity of the chloral given was one hundred grains, and of morphia one grain and one-sixth, in the space of an hour and fifteen minutes. Previously to the administration of chloral, the pupils were contracted to a point: an indication, of course, that the previous mixtures had been absorbed, but, as we have seen, with the effect only of increasing the excitement. Considering that the preparations of opium given previously had not conduced to somnolency, I attribute this condition to the chloral-hydrate chiefly, if not entirely. In another obstinate case of delirium tremens, in which the usual treatment by digitalis, morphia, etc., was ineffectual, I had recourse to chloral, repeated every ten minutes till one hundred and sixty grains had been taken. The patient then fell over, and, after sleeping for seven hours, was, on awaking, altogether a changed man.

I may add that, during the first two doses, there is always increased excitement, the patient becoming very garrulous—indeed, *intoxicated*, to all appearance; but this soon gives place to thick speech, inarticulate mummings, and peaceful sleep.

J. FARRAR, L.R.C.P.Ed., etc., Morecambe, Lancaster.

### PILOCARPIN, THE ACTIVE PRINCIPLE OF JABORANDI.

A MORE elegant and effective way of introducing the active properties of jaborandi into the system than that proposed by Dr. Coghill as a therapeutical remedy in hydrophobia (*BRITISH MEDICAL JOURNAL* of January 5th) would be by the hypodermic injection of the alkaloid named by its discoverer, Merck, pilocarpium natrium (muriate of pilocarpine). It consists of transparent white crystals, and forms an easy and clear solution in equal parts of water. A hydrochloric solution of two per cent. is used for subcutaneous injection, one gramme or sixteen minims of which are equivalent to five *grainnes* or eighty minims of the infusion of jaborandi-leaves. About one to one-

and-a-half grammes (of this solution), containing one-third to half a grain of pilocarpin, are injected. From two to ten minutes hardly elapse before the effects of the pilocarpin begin to be seen. If injected in the temporal regions, the effects show themselves very quickly; but if in the external sides of the lower extremities, a much longer interval ensues. At first, a sudden increase in the salivary secretions takes place, which reaches its acme after about fifteen minutes, and lasting generally from about one-and-a-half to two hours, producing from about half a pound to a pound and a half of a thin liquid saliva. Almost about the same time, the pulse-frequency rises about ten to twenty beats in the minute, combined with reddening of the face and a feeling of warmth, which increases to strong perspiration. This begins at the roots of the hair of the head, and extends over the face, neck, chest, body, arms, and lower extremity, and continues about an hour and a half, and may easily be protracted to three hours by wrapping the patient in blankets. The amount in weight of the perspired fluid is about two to four pounds. The lacrymal glands secrete at the same time very strongly. After a few minutes, the pulse beats more slowly, and gradually falls with the ending effects of the pilocarpin until it has reached its former intensity. The temperature, measured in the axilla, rises from about one to two degrees Fahr., falling afterwards with the pulse, and sinking sometimes from two to four degrees Fahr. under the original height. Pilocarpin seems to act by widening and lessening the tension of the arteries, and acting on the nervous centres of the sudoriparous and salivary glands. Atropia is a powerful antidote to pilocarpin. An injection of 1-120th of a grain of atropia arrested all the effects of the common dose of pilocarpin. Even five or six drops of a one per cent. solution of atropia, dropped into the conjunctival sac, completely negated an injection of pilocarpin.

Pilocarpin does not cause the evil after-effects of jaborandi, such as vomiting, vertigo, nausea, etc. Like jaborandi and its class, pilocarpin has no specific therapeutic effects; it merely acts as a powerful diaphoretic and dialagogue. Any evil effects that may be produced by its administration, as vomiting, etc., which rarely occur, can easily be suppressed by the inhalation of a few drops of nitrite of amyl.

LOUIS HENRY, M.D., Manchester.

## SURGICAL MEMORANDA.

### FOREIGN BODIES IN THE EAR.

As a pendant to the case of Mr. Habgood, the following may be considered worth recording.

In May last, a female patient, aged 38, presented herself at the Central Throat and Ear Hospital, requesting that I would remove from her left ear a piece of black lead, which she stated to have introduced when, as a child aged 8 or 9, she had been playing with a pencil belonging to her father, who was a carpenter. She graphically described the attempts to remove it with crochet-needle, bent hairpins, etc., by a doctor, and also by her mother; and she had a most vivid recollection of intense suffering. On examining the ear, I found it blocked with impacted wax, but I expressed doubts as to the foreign body being still there. Somewhat to my surprise, however, as well as to that of my assistant, Mr. Douglas Hemming, and others who were present, with exit of the first syringe-full of warm water, something clicked on the bottom of the glass held to receive it. This proved to be a piece of black-lead pencil, such as is used by carpenters. It lies now before me; its edges are quite square, blunted at one end with use, and rough where broken off at the other; it measures three-eighths of an inch in length.

This patient came to the Hospital in consequence of the success which had attended similar treatment of the child of a neighbour, in whom the foreign body had been a glass bead.

LENNON BROWNE, F.R.C.S. Edin., Weymouth Street.

### FRACTURE OF OS CALCIS BY MUSCULAR ACTION.

IN December 1876, M. N., a spare healthy woman, aged 42, while leaving a shop, made a false step, forgetting that the shop and street were not on the same level. The street slopes very much, so that the depth of the doorstep down into it varies from three and a half to eight and a half inches; and probably the woman strode off a height of not more than six inches. She was sober, and not carrying any weight. She exclaimed, "I've put my ankle out". She did not fall, but without assistance limped home, a distance of about a hundred yards. She had never injured the part before. On examining her shortly afterwards, a fragment of bone, with the skin tightly stretched over it, was seen at the back of the leg, two inches and a half above

the point of the heel. Below this, the cord of the tendo Achillis was wanting. The lower edge of the fragment was a little above the level of the lower end of the internal malleolus. It was about one inch transversely, and had been torn off the posterior surface of the os calcis, where a cavity could be felt. The whole depth of the bone had not been torn away, but only the upper three-fourths; and the inferior edge of the fragment had been tilted backwards so as to project against the skin. This edge could be bent down for a quarter of an inch; but, on leaving off the pressure, it sprang back again. The skin was not bruised, and there was no other injury.

The usual treatment for ruptured tendo Achillis was adopted, and in about eight weeks she was able to walk without limping, and only complaining of some loss of spring. Two days after the accident, there was great swelling, and the skin over the fragment was so tight that tenotomy suggested itself; but there appeared this objection, that, if the tendo Achillis were divided, the torn away piece might be left without sufficient vascular supply. A few days later, a small slough formed, leaving a superficial ulcer of the size of a shilling, which soon healed under red lotion.

The interest of this case is its rarity. A note at page 282 of Holmes's *Principles and Practice of Surgery* states: "It is said that the tuberosity has been torn from the rest of the bone by muscular action; but this seems dubious." In this case, however, no other explanation can be made.

J. W. ANNINGSOON, Burnley.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CONSULTATIONS.

JANUARY 17th, 1878.—*Multiple Sarcomata in a Boy*.—Mr. HOLDEN brought into the operating theatre the same patient who was exhibited by Mr. Butlin at the Pathological Society on December 4th, 1877 (see BRITISH MEDICAL JOURNAL, vol. II, 1877, p. 807). Since that date, another sarcoma has developed below the right trochanter major, and a second on the right ulna. The right testicle has become still smaller. Mr. Holden remarked that whereas all the former growths which he had removed were in the subcutaneous cellular tissue, the most recent was, to all appearance, a subperiosteal growth intimately connected with the ulna. He was not in favour of any further operation.—Mr. SMITH remarked that as all Mr. Holden's previous operations had been attended with much temporary benefit, he advised the removal of the now existing tumours if they were growing rapidly.—Mr. WILLETT agreed with Mr. Smith, not deeming partial excision of the ulna to be a desperate operation.—Mr. LANGTON was not in favour of removal of the tumours; and Mr. BAKER did not think operative interference advisable at present.

*Swelling on Tibia: Nature Doubtful*.—Mr. THOMAS SMITH asked advice in the case of a married woman, aged 26. Four months ago, she struck her knee against some hard substance. Shortly afterwards, a lump appeared just below the right knee to the outer side of the spine of the tibia. It was now red and tender, and there was an indistinct sense of fluctuation on pressure. There was an enlarged gland in the groin. The leg was very painful at night. There was no evidence of syphilis. Mr. Smith wished to know whether the swelling was inflammatory and due to injury, or a new growth. If the latter, it should be at once removed.—Mr. HOLDEN thought that the case should be watched for a few weeks, then an exploratory puncture should be made. He believed that there was deep fluctuation on pressure, and that the swelling was inflammatory.—Mr. SAVORY agreed entirely with Mr. Holden. No good, but much harm, would ensue from interference at present.—Mr. WILLETT was of opinion that the swelling was a new growth, being very well defined.—Mr. LANGTON believed the disease was inflammatory. He recommended an exploratory incision at once, with removal of the tumour, should one be thereby detected. The incision would, on the other hand, do no harm if the affection proved to be inflammatory.—Mr. BAKER agreed with Mr. Langton's suggestion, but advised waiting for a week.—Addressing the students present, Mr. SMITH remarked that the case was most instructive, and hoped that they would watch it, and form their own judgment on the nature of the swelling, which he intended to explore.

*Ulcer of Soft Palate.*—Dr. LAUDER BRUNTON exhibited a girl, aged 13. Her soft palate was deeply ulcerated, and thus divided into two halves. The edges of the ulcer were ragged, and its surface dull yellow; the pharynx was granular and beginning to ulcerate. Eight months ago, the child had an enlarged gland under the chin. For two months, she suffered from dysphagia and constant hawking. Her father was quite healthy; her mother, phthisical. There was no history of syphilis. Dr. Brunton observed that, had the girl been twenty-three instead of thirteen, he would have believed the ulceration to be syphilitic. He could obtain no history of hereditary syphilis, and believed that the ulcer was strumous. He intended to apply tincture of iodine locally, and give cod-liver oil and iron.—Mr. HOLDEN believed that syphilis must have existed in the parents, possibly in the grandparents.—Mr. SAVORY believed the disease to be strumous.—Mr. SMITH did not believe it due to syphilis, but recommended the administration of iodide of iron, as it was beneficial both for struma and for venereal disease.—Mr. LANGTON had seen a similar doubtful case, which improved under treatment within the hospital, but got worse when discharged.—Mr. BAKER said that he would consider the patient to be strumous, and not syphilitic, even if she were twenty-three.—Dr. BRUNTON intended to administer iodide of potassium for a few weeks, and then, should there be no improvement, he would try the iodide of iron.

*Neuralgia of Upper Extremity.*—Mr. WILLETT brought forward a woman, aged 47, who for eighteen months had severe neuralgic pains in the right shoulder and upper arm. The pain commenced immediately on the healing of a small axillary abscess, the cause of which was quite unknown. The patient could neither use her arm by day nor sleep at night, on account of the pain. No disease of the humerus or shoulder-joint could be detected, and treatment suitable for rheumatic arthritis had failed. Mr. Willett believed this to be an instance of pure neuralgia. He proposed either to apply the actual cautery over the roots of the brachial plexus, as Mr. Thomas Smith had recommended, or to stretch the nerves of the arm, on Mr. Callender's principle.—Mr. HOLDEN recommended galvanism. Stretching all the nerves of the arm would be formidable, and selecting any would be difficult in the live subject.—Mr. LANGTON was in favour of the actual cautery followed—or substituted, perhaps—by subcutaneous injection of atropine.

*Fungating Growth of Forearm.*—Mr. LANGTON, in the absence of Mr. Savory, asked for advice in the case of a woman, aged 55. Two years ago, when in perfect health, she noticed a hard swelling on the back of the left forearm, immediately above the wrist. A few months later, she was troubled with obstinate sore-throat. The swelling, at first of the size of a pea, had grown very rapidly. It was now a large fungating mass, of the size of a small cauliflower-head; the skin around was not hardened; the arm was cedematous; but no enlarged glands could be detected. There were horse-shoe shaped tubercular patches on the forehead, legs, and right wrist.—Mr. SAVORY was of opinion that the disease was a sarcoma, and believed that the limb should be removed at once, unless it were thought advisable to wait till the oedema subsided.—All the surgeons were in favour of immediate amputation above the elbow.

## REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

### THE SILBER OIL AND GAS LIGHTS.

THE importance of any great improvement in artificial light is so considerable, not only for purely medical purposes, such as microscopical lamps and reading lamps, but from general hygienic considerations in lighting of wards and living rooms, that considerable interest attaches to the success which has attended the practical study of this question by Mr. Silber, and the undoubted improvements which he has introduced.

The advantages derived from the use of a lamp which, while giving the maximum amount of light, is unaccompanied by the dangers and inconveniences attendant upon the employment of the means of obtaining artificial light in vogue until within quite a recent period, and now by no means effete, are, we think, likely to be universally appreciated.

To obtain this laudable result, Mr. Silber has devoted unwearied attention to the study of the phenomenon of light, and the laws which govern it. So successful have been his labours, that the invention, which bears his name, changes the old blue and yellow lights into a pure white unwavering flame. By reason of the superficial study given to the laws which regulate combustion, till within recent years, lamps were constructed on a system which rendered the union between the hydrogen and carbon of the oil or gas and the oxygen of the atmosphere imperfect; the defective apportionment of these agents resulted in halting combustion, dull red illumination, smokiness, and in the circulation of deleterious chemical compounds in the room. Although means were carefully taken to furnish with regularity the oil or gas to support the flame, insufficient attention was given to the maintenance of the requisite amount of air to aid combustion.

The improvement in this respect can readily be seen by a trial of Mr. Silber's argand lamp. In this there is an exactly measured amount of air to feed the flame, and its temperature is adjusted before it is required. A warm current of air is made to flow to the lower part of the flame, and a colder current to the centre of the burner, thus supplying the exact need for obtaining and continuing perfect combustion. The uniformity of the flame, which is admirable, is caused by dropping a narrow tube of metal, duly proportioned to the argand ring, into the centre of the ring; it acts as a continuous director of the air-draughts to all parts of the flame. In the absence of this ring, the argand yields a poor and unsteady light; with it the flame loses the broad blue colour of the base, and becomes wholly white, and obviates the cause of annoyance experienced by the worker under a flickering light. A further improvement in this lamp is that it allows the oil to be, as it were, volatilised before consumption. As in other lamps of the kind, the wick does not touch the inner metal tube; the mere extremity only perishes, burning for weeks without trimming, it being only necessary to brush the top before applying the match. These lamps do not require any increase in the quantity of oil, and will consume either mineral, animal, or vegetable oils. Preference is, however, given by the inventor to petroleum and colza. The Silber argand gives off no smell, and secures immunity from explosion, even when petroleum is used. It is also cheaper by 40 per cent. than coal-gas. The oil can be laid on like gas to every room in the building from a cistern in the roof.

In the use of gas, the importance of the burner is paramount; experiments have proved that large quantities are wasted by the employment of the common kinds. Mr. Silber's burner has been publicly shown to be the best hitherto invented. It consists in the adaptation of his principle to the argand burner. By means of his properly regulated air-currents, the Silber tubulated gas-burner has, when photo-metrically tested, yielded the highest illuminating power of which gas is capable. The Silber bat's-wing gas-burner is described as being a double bat's-wing burner, the lower one delivering into a small metal chamber a quantity of gas, to be issued by a larger burner of steatite at the top: the issue cannot possibly exceed the amount admitted by a small orifice below. The steadiness, clearness, and softness of light is enhanced by the use of the opaque white or opalescent globes. Lamps and globes are specially manufactured for ships' cabins, marine and railway light signals, carriage-roofs, platforms, etc.

The improvements have been successfully brought to bear upon the moderator lamp, which burns mineral oil, and the common lamps. By affixing Mr. Silber's burners to these, not only is the quality of the light improved, but also a great saving of oil is effected. Lamps of a great variety of kinds are manufactured, as we had occasion to note, at the Silber Light Company's premises, Whitecross Street, London. Among them, we may instance a reading-lamp of admirable design; lamps specially adapted for assisting at microscopical investigations; domestic lamps of all kinds, embellished by every variety of ornamentation. Before concluding, we must mention that the Silber light, when decomposed by a prism, owing to perfect combustion, casts upon a screen the same spectrum of colours as does a ray of the sun; a consequence of this is, that the finest combinations of colour can be discriminated by artificial light, and investigations in which such an object is necessary need not now, as hitherto, be discontinued at the close of the daylight hours.

In conclusion, we would point out that Mr. Silber's lamps are valuable in assisting ventilation, and in other sanitary aspects their advantages are great: for it is of course evident that the minimum of carbonic oxide and vapour is produced, and an absence of injurious chemical agents insured, where there are perfect combustion and a regular pressure. As far as practicable, the sulphuric acid created by deficiencies in the combustion of gas is eliminated. Indeed, in the whole of Mr. Silber's inventions, there is noticeable the only reliable factor of success, a complete attention to, and adoption of, natural laws.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 26TH, 1878.

THE LOST MEDICAL SCHOOL.

WE publish in another column two important contributions to the further discussion of the question whether the profession at large, and the medical graduates of Oxford in particular, the friends of the University, and the believers in scientific progress and culture, ought any longer to stand by quietly and witness unmoved the annihilation of the School of Medicine at Oxford. The letters of Dr. T. K. Chambers and of Dr. Payne respectively may, we suppose, be taken as good typical examples of the view likely to be taken by Oxford graduates belonging to different scientific generations, and under the influence of somewhat differing schools of thought, but each alike representing those opinions with special ability and force. Whatever cause Dr. Chambers may espouse, he is sure to plead it with candour, and to maintain it with vigour. Making due allowances for the energy which is natural to his character, and which betrays itself here rather in the excellent form than in the force of the argument, it is surprising to see how little he has to say in defence of the cause which he advocates, how short is his argument and fragile is its texture. We have unfolded a case of no small weight and magnitude. We enumerated last week a series of offices to provide for medicine its proper place amongst the studies of a liberal and great university. We gave a brief schedule of the endowments which should be the birthright of this generation of medical students in Oxford; and we glanced, only slightly, at the immense advantages which must accrue to medicine, on the one hand, from its natural alliance with the highest teaching of cultured arts and letters; and on the other hand, to the University, from the living force and practical direction which would be given to its biological departments of study by the presence in the University of a body of students in whose work these studies would fructify, for whose use they are mainly intended, and from whose ranks investigators of biological science have always, at all times and in all countries, been mainly recruited. Medicine has always been a poorer sister of the other professions in Oxford, and they have availed themselves of her very poverty and weakness to despoil her scanty heritage, and not only to take from her her rights and to drive her from the field, but, in the last instance, to erase from official publications the very name of the Faculty of Medicine.

All this, Dr. Chambers passes over with a light hand, and sets forth his vindication of the system by informing us that, in his opinion, the Radcliffe Infirmary, containing two hundred beds, is insufficient for clinical teaching, and does not afford adequate materials for the practical instruction of the medical student. Now it is, of course, in one sense, advantageous to an advocate to be able, as is said, to put his argument in a nutshell, but it is well that the nutshell should not be so frail that it can be crushed between the fingers; and never, perhaps, has a more attenuated shell of an argument been presented, or one which should more promptly be cracked by the forces which ought to be at work to preserve, for the benefit of medicine, of science, and of culture, the Medical Faculty of such an university as Oxford. The

answer will, we feel sure, occur to every mind, and it is admirably expressed in the letter of Dr. Payne, when he says, "clinically speaking, it is the school which makes the hospital, and not the hospital the school". Such an objection, indeed, from the mouth of a physician, comes strangely enough; for it must, indeed, be a singularly managed hospital, and existing under strange conditions of totally abnormal states of health, which does not supply a fair amount of medical material in so large a number of beds. The letter of Dr. G'lynn Whittle expresses an opposite experience to that of Dr. Chambers. We know of no special forms of medical disease which are not as likely, nay as sure, to appear in a county hospital well administered as in any other; and in respect to surgical cases, Dr. Payne's observation is obviously true, that the character of the surgical cases depends, to a very large extent indeed, upon the importance of the school teaching, upon the reputation, character, and energy of the clinical professors, and upon the stimulus which the school gives, on the one hand, to teachers of reputation, and on the other, to persons in the surrounding county to send thither surgical cases of interest and importance. Dr. Payne points, as everyone will in imagination direct his mind, to such hospitals as those at Halle, with a similar number of beds and with a less surrounding population, which Volkmann has at this moment made illustrious by the extent and importance of its surgical clinic and by the lessons which have been derived from it. Würzburg, Heidelberg, Göttingen, and Halle protest against the validity of the assumption which Dr. Chambers thinks sufficient to justify the despoilment of the profession and the abandonment of the Medical Faculty, which ought to be one of the chief ornaments and one of the highest boasts of the University from which it has been expelled.

We earnestly ask for the careful perusal of the able and exhaustive letter of Dr. Payne. No doubt the prejudice, especially the unconscious bias of personal habits and thought and surroundings, and possibly also the undetected influence of personal interests and associations, may still lead some minds, and especially of men accustomed to take a leading interest in metropolitan schools and hospitals, to very readily accept the self-flattering doctrine that London, or towns such as London, must be the site of great medical schools; and that the one difficulty suggested, which gives to London its superiority, may excuse the crushing of the Oxford school in avowed deference to London schools. Such ideas have always had too much influence in the metropolitan mind; they are likely for a long time to find only too ready an echo in the words and thoughts of influential Londoners. This, however, is, we suggest, a parochial and shallow view. Great masses of population are not essential, although they are advantageous, to great schools. London and other metropolitan cities will never fail to realise the advantage of possessing such a wealth of material, and will never cease to attract the great majority of students. There is no thought of displacing the metropolitan schools; but, on the other hand, no one can doubt, who seriously considers the question, that, did Oxford possess the *personnel*, as it has the funds and material, for teaching of an unapproachably high character in all the theoretical and scientific departments of medicine and its collateral sciences; had the medical school not been despoiled and crushed, mocked with an incomplete organisation which is not available to meet the formal requirements of the examining bodies, and stifled beneath official arrangements which give to it only the form without the reality of medical education,—it would be the natural selection of persons desiring specially to cultivate the higher scientific education which belongs to the first class of medical education, and would attract a considerable and important proportion of medical students. There would probably be necessary arrangements, of which a dozen modifications may be suggested, and which require, indeed, no official help. If men chose to supplement their clinical

experience by a residence in the great centres of population during twelve out of the forty-eight months which are the minimum period of the medical curriculum, this would neither endanger the integrity nor interfere with the course of teaching in the Oxford Medical School. It is, in fact, a question of detail, which would offer no difficulty whatever in solution, and would furnish in practice half a dozen solutions for itself. At any rate, it appears to us in the highest degree presumptuous and unpatriotic to take measures such as that which has been taken to prevent the medical faculty of Oxford from fulfilling the ordinary requirements of the examining bodies, which is of itself enough to drive away all medical students from its doors; and then to justify it on the ground that an infirmary of two hundred beds would be too scanty to complete their clinical experience.

It would be, perhaps, too much to expect that nothing could be urged in favour of any abuse, however flagrant, and we must expect to hear further arguments advanced for the sad maltreatment which has befallen the interests of medicine in the University of Oxford; but, if none other than these can be alleged, the case may, we think, be said to be won before the court of common sense and common justice almost as soon as the pleadings are opened. Dr. Payne has said rightly that this is a question which should on no account be argued on personal grounds. That view we have already expressed, and we reiterate it; and, indeed, we feel that if any personal feelings are to avail, they must tend to arrest the progress of the movement for reform which has, we trust, now been commenced in earnest; for the personal esteem in which we feel sure that the profession at large regard both Dr. Acland and Dr. Rolleston must, up to the present time, have done much to arrest inquiry and to forbid complaint in a case in which it can no longer be doubted that both are urgently needed.

#### CHOLERA.

THE latest news from Egypt confirm the report that cholera has broken out in Mecca and Jeddah, and gives the information that the deaths from the disease averaged seventy daily in the first named town and thirty in the last named. There is still some uncertainty whether this outbreak is to be regarded as the result of a casual introduction of cholera into the Hedjaz, or whether it is a sequence of the epidemic of 1875-76 in India, and, as such, an incident in the progress of a more general dissemination of the disease. It is known that cholera has been extending in the countries eastwards and northwards of India; but as yet there is too little information to gauge rightly the significance of the extension in these directions. It is discreditable to the Imperial Government, and especially to the Indian Government, that the public information on this subject should be so imperfect, and that not until Europe is actually endangered does it become possible to ascertain the movements of cholera beyond the boundaries of India. The Indian Government seems to regard the faculty of disseminating cholera outside the limits of its dominion without warning as a sacred and withal secret right; and, when the disease begins a world-wide migration, this Government then loudly disavows its responsibility for the movement, and endeavours to shelter itself under certain eccentric opinions as to the nature and mode of propagation of cholera, which are inconsistent with the vast mass of Indian experience on the subject, and totally opposed to European knowledge. The Indian Government, in fact, is acting in this matter like an individual who, having fired a loaded pistol from his room in the direction of the window, protests against being held responsible for the bullet when it has passed into the outer air. We do not forget that the Local Government Board, in its recent annual report, writing from information in its possession, refers to a recent extension of cholera into Afghanistan and Beloochistan as giving it some anxiety; and to this extent the Imperial Government may receive credit for being awake to the contingency of pandemic cholera. But we feel justified in doubting, from the manner of the reference and in face of this outbreak of

cholera in the Hedjaz, whether the information which the Local Government Board may have, and which presumably is derived from the Indian Government, is such as meets the requirements of the Imperial Government in its international relations. It is in these relations that the present outbreak in the Hedjaz has for the moment primary importance. The International Sanitary Conference held at Vienna in 1874 was called together in view of such a contingency, and we are now about to have put to the test—or rather the test is now being applied as to—the practical value of the conclusions of that Conference, in so far as these related to the introduction of cholera into Europe.

It may, perhaps, be well to recall here generally the nature of the Conference's proceedings and the principal conclusions at which it had arrived. Let it be premised that the Conference was a medical one, and that it formed an excellent representative body of medicine in Europe. First, it dealt with certain scientific questions, and affirmed the endemicity of cholera in India, and in India alone; the transmissibility of the disease by man coming from an infected locality, subject to certain local conditions; the transmissibility of the disease also by personal effects which had served for the sick of the disease, and by water. The Conference next proceeded to deal with quarantine as a means for excluding cholera from a country or a locality. In this relation, it condemned land-quarantine as impracticable and useless; and in respect to quarantine as it affects Europe, it made an important distinction. Quarantine, as means of shutting out cholera from Europe when impending from the Red Sea or by way of the Caspian, was approved; but quarantine in Europe, when the disease had once invaded the Continent, was condemned on the same ground as land-quarantine. For European ports, a system of medical inspection was recommended very similar to that which is adopted in English ports; and if quarantine should be carried out by any maritime nation on the Continent, a scheme much modified from the old practice was agreed to.

We are now face to face with one of the contingencies contemplated by the Conference, a new threatened invasion of Europe by cholera along the route of the Red Sea. The Egyptian Government is understood to have founded its measures of protection, not only for its own provinces, but also for the basin of the Mediterranean, on the recommendations of the Conference; and thus it happens that the conclusions of the Conference on this vital question are now being subjected to the test of actual experience. The result is awaited with the deepest interest. The Mecca pilgrimage is over, and the arrival off Suez of the first vessel bringing returning pilgrims is announced. It will not be long, therefore, before we shall know whether the conclusions of the Conference of 1874 as to the arrest of cholera on the Red Sea route—a conclusion which, it should be noted, repeated the conclusion of the Constantinople Conference of 1866 on the same question—will be sustained in practice.

M. FELTZ has submitted to the Paris Academy of Sciences a note, affirming the presence of cryptogamic germs in the blood of patients suffering from typhoid fever. These germs appear to be capable of vegetating in flasks containing pure air alone.

WE are asked by the Secretary to the Subcommittee of the Royal Medical and Chirurgical Society on the relations of diphtheria and croup, to state, on behalf of the Committee, that they are anxious to obtain the notes of any case in which the formation of false membrane in the air-passages has succeeded upon a definite exposure to cold; and they will be greatly indebted to any gentleman who will favour them with such information. They would also be glad of a specimen of the larynx and trachea, or of expectorated false membrane, from such a case, either in a fresh state, or preserved in spirit, Muller's fluid, or other suitable reagent. Cases and specimens may be sent to Dr. Greenfield, the Secretary to the Committee, 95, St. Mark Lane, W., or at the Society's Rooms, 53, Berners Street, W.

DURING the ensuing year will be commenced a new publication, entitled *Deutsches Archiv für Geschichte der Medizin und Medicinischen Geographie*. The new journal will be published by the house of Hirschfeld, in Leipsic, and will appear in quarterly parts. The first number is announced for March. The list of editors is very extensive, and promises a valuable series of papers, which will undoubtedly possess considerable interest for those cultivated physicians who desire to retain a hold upon the historical progress of medicine, its historical pathology, medical geography, topography, and chorography, and other subjects connected with medical geography and history. The acting editors are Heinrich Rohlf of Göttingen, and Gerhard Rohlf of Weimar.

#### THE LATE PROFESSOR STOKES.

THE *Deutsche Medicinische Wochenschrift* of last Saturday contains a brief, but highly appreciative, note of the late Dr. Stokes, of which the following is a translation.

"William Stokes, the great Irish physician, whose severe illness we lately reported, died on January 7th, at the age of seventy-four. German medical men know and value his writings, the first of which—*Introduction to the Use of the Stethoscope*—appeared as long ago as 1825. His lectures on the *Theory and Practice of Medicine, on Diseases of the Chest*, and on the *Diseases of the Heart and Aorta* (translated by Lindwurm), are complete models. In common with his friend Graves, he was one of the happiest reformers of the treatment of fever. Finally, he was one of the most excellent of teachers; and, as a colleague, he was the model of an English gentleman in the best sense of the word."

#### THE PREVENTION OF SMALL-POX EPIDEMICS.

DR. COLLIE, in a paper which he read recently at the Epidemiological Society, expressed his disbelief in the compulsory vaccination laws. He would make vaccination voluntary, but would insist that it be efficient; and, in order to accomplish this, he was of opinion that it should be performed by State officers solely, and be held to include revaccination about puberty. On the subject of the vaccination laws, there may fairly be a difference of opinion as to whether they should be compulsory or not; but it seems to us that it would be inadvisable at present to make any alteration of the existing statutes. However, the necessity for revaccination cannot be too strongly insisted on, and we fully agree with Dr. Collie that efficient vaccination should be held to include revaccination about puberty. The experience of every succeeding epidemic of small-pox shows, in the clearest possible manner, the immunity from this disease which those enjoy who have been revaccinated; and, although there are one or two cases of small-pox after revaccination on record, the absolute immunity conferred on those engaged in attendance on the sick, when revaccinated, forms the most conclusive proof of its efficacy to ward off this loathsome disease; and we do not think that we are stating more than the facts of the case warrant us, when we say that, were systematic revaccination about puberty enforced with the same care as primary vaccination in infancy is at present, small-pox would be almost unknown among us.

#### SMALL-POX AT HARWICH.

THE epidemic of small-pox at Harwich still raged up to the 23rd instant. Ten fresh cases had been admitted to hospital, making in all forty-nine received since the 2nd instant. Ten deaths occurred, and eight patients have been discharged. The majority, however, of persons under treatment, we are happy to learn, are convalescent. These figures show that there is scarcely any abatement of the disease. Almost one-half the cases admitted are confluent. The Sanitary Committee meet daily, to receive reports and see that every means possible are taken to combat the disease. The sufferers are removed from their homes to the hospital immediately after dark, and all communication between the hospital and the town is avoided as far as practicable. In the matter of vaccination, there is a reprehensible supineness on the part of the townsfolk. Two cases were brought under the observation of the medical superintendent of the temporary hospital:

one was that of a man forty years of age, taken ill at Christmas, and admitted to the hospital; about sixteen days afterwards, his son, aged six years, was sent in, and the father did not know whether the child had been vaccinated. Examination showed that vaccination had not been performed, and, as might have been expected, it proved a confluent case. There were many other similar cases of people living in the midst of a small-pox epidemic neglecting the only means of security; although people are now presenting themselves more freely for revaccination, and seem to begin to recognise the importance of it.

#### LONDON HOSPITAL.

It has been decided to increase the medical staff of this hospital by the appointment of an additional Assistant-Physician. The ever-increasing number of out-patients has necessitated this step. We are glad to see that the authorities are alive to the desirability of an adequate staff; for even under the most favourable circumstances, the sick poor who apply to hospitals as out-patients, have many hardships to put up with, and assuredly not the least of these is the great length of time they must often wait in order to be seen. There are two candidates already in the field—Dr. Gilbert Smith and Dr. Francis Warner. The latter gentleman has held the appointment of Medical Registrar for the past twelve months, and was, moreover, re-elected, without the formality of advertising, for the current year a few weeks ago. Such an acknowledgment of his work having been well done, which the House Committee of the Hospital hereby gave him, will, no doubt, exercise a great influence on the decision at which they will arrive when the election to this vacancy is formally considered. The appointments of registrars are now the acknowledged stepping-stones to the higher appointments on the staff. The London Hospital can ill afford, either from a public or from a professional point of view, to ignore the claims which its junior officers make for themselves by careful work in the subordinate posts.

#### ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

AT the annual general meeting of this Association, on Wednesday evening, January 16th, at their rooms in Chandos Street, the following gentlemen were duly elected office-bearers for the year 1878, their names having been previously proposed by the Council. *President*: S. J. A. Salter, M.B., F.R.S.—*Vice-Presidents*: W. A. N. Cattlin, Esq.; Samuel Cartwright, Esq.—*Treasurer*: Alfred Coleman, Esq.—*Honorary Secretary*: J. Hamilton Craigie, Esq.—*Council*: Hamilton Cartwright, Esq.; T. Edgelow, Esq.; F. Fox, Esq.; J. Fairbank, Esq.; G. Gregson, Esq.; W. D. Napier, Esq.; J. H. Parkinson, Esq.; N. Stevenson, Esq.

#### THE NORTHAMPTON INFIRMARY.

THE vacancy, caused by the resignation of Dr. Francis, in the post of Honorary Physician to this institution, has not yet been filled up. Advertisements have appeared informing intending candidates that the election would take place on Saturday last; but although the Governors duly assembled, no appointment was made. The only candidate was the Senior Surgeon to the Infirmary. Preferring medicine to surgery, this gentleman resigned his present office to enable him to compete for the vacant Physicianship. He is M.D. of the University of London, M.R.C.P.Lond., and F.R.C.S.Eng.; so that it is not to be wondered at that no one opposed so highly qualified a candidate. Unfortunately, the Northampton Infirmary is an unreformed corporation, so far as its laws are concerned, and these appointments are still vested in all the Governors, so that a candidate has to undergo the great expense of canvassing all the county. On Saturday, the Governors decided to postpone the election of a physician for six weeks, in the hope, we understand, that some more highly qualified candidate may be induced to come forward. We venture to assure the Governors in question that the authorities of the London hospitals are perfectly satisfied with such qualifications as we have enumerated, probably for the reason that they know not where to look for better ones. Unless there is

something behind, of which we know nothing, the action of the authorities in this case appears unaccountable. Under the circumstances, it is probable no other candidate will offer himself for the vacancy.

#### THE HOSPITAL SUNDAY FUND.

THE recently appointed Council of the Hospital Sunday Fund met, on January 10th, at the Mansion House, under the presidency of Sir Sydney H. Waterlow, M.P. The members of the committee of distribution were re-elected; and two vacancies occurring in the general purposes committee, by the retirement of the Rev. G. Bowden and Mr. R. B. Carter, were filled by the election of the Rev. J. Baker, as representing the Wesleyan interest, and Dr. J. G. Glover. Sir Rutherford Alcock submitted a motion having for its object the admission of Truss and Surgical Aid Societies to a participation in the funds. In the course of his remarks, he pointed out the claims that such institutions had upon the Fund, and instanced the City of London Truss Society, the National Truss Society, the Surgical Aid Society, and others. The Rupture Society might, perhaps, be excluded from the list, as it possessed an invested fund of £30,000. He claimed for the Societies he had mentioned a share in the Fund, because they were engaged in a meritorious work, and partaking of the nature of the work done at the hospitals. The chairman raised the objection that Rule 4, which guided the distribution, only included hospitals and dispensaries, and, therefore, the Societies referred to in the motion could not be included until the resolution was altered for that purpose. Dr. Glover contended that such institutions were hospitals. He could not see but that institutions which treated hernia were hospitals; they gave mechanical support, without which the patient was in danger of his life; and, in many instances, advice. He could, as a medical man, give testimony to the value of those institutions, and was sure that they could not do better with the Fund than to give a fair proportion to them. A long discussion ensued, in which Mr. Thompson Hankey, M.P., Mr. T. Turner, Rev. T. J. Simpson, Mr. Hansard, Bishop Claughton, with others, took part. Dr. Hamilton suggested that the managers of hospitals should be recommended to distribute instruments. The chairman remarked that he was treasurer of one of the largest hospitals, and knew that the Charity Commissioners would not permit the managers to expend one penny of the funds in instruments; what they did in that respect was done out of the Samaritan Fund, for which they solicited subscriptions. After some further remarks, Mr. Jabez Hogg said the Truss and other such Societies were looked upon in hospitals as an injury to Samaritan Funds, by drawing large amounts that would otherwise find their way to them. Dr. Glover moved an amendment, expressing the opinion of the Council that Rule 4 admitted Truss and Surgical Aid Societies. The Rev. Canon Miller seconded the amendment, which was, however, withdrawn. The same course was pursued in reference to several others, and in the end it was resolved, "That the question of admitting surgical and provident societies within the limits of Rule 4 be referred for consideration to the constituency of the Fund, and that the Lord Mayor be requested to call an early meeting of the Council for the purpose of ascertaining what course it would be desirable to recommend the constituency to adopt with regard to the question".

#### QUACKERY IN LIVERPOOL.

MUCH regret has for some time been felt by our professional brethren in Liverpool, that the same vigorous measures have not been adopted in that town against the advertising quacks, that have been so successful in Manchester and Birmingham. The largest seaport in the kingdom contains, as might be expected, a great number of these gentry, whose audacity is quite unprecedented. The amount, too, of obscene literature which circulates in Liverpool, under such titles as "A Word with You", "A Treatise on Marriage and Self-control", "Catalogue of the ——— Gallery of Anatomy", etc., is as great as it is pernicious. If one may judge from the style in which these individuals live, the pursuit is a very profitable one, of course at the expense of

the ignorant and credulous. But there is one matter in connection with this subject, which demands instant attention, not so much from the local authorities as from the General Medical Council, the University of Edinburgh, and the Colleges of Physicians and Surgeons of that city respectively. One of the individuals to whom we have alluded, and who takes the lead in brazen effrontery, has been for some time past assisted by a duly registered medical practitioner. There was some difficulty in identifying the latter, the surname being a common one. Recently, however, the individual disclosed his identity by returning to the editors of the *Medical Directory* his address, which was that of the leading quack, and may at this moment be seen posted up in rich profusion on walls, and hoardings, and in urinals. A complaint was sent to the General Medical Council, as also to the licensing bodies whose diplomas had been so much misused; but a higher power intervened, and the individual recently terminated a very discreditable career by a premature and somewhat sudden death. Were this all, it would be enough cause for regret; but, unfortunately, it is not. We are informed, on reliable authority, that a successor has been found, whose name appears on the door underneath that of the quack, with the title of "surgeon" below. The name of the gentleman in question appears in the *Medical Register* for 1877, with the qualifications M.D., L.R.C.P., and L.R.C.S., all of Edinburgh. Information has (we are told) been sent to the General and Scotch Medical Councils, as well as to the University and the Colleges of Physicians and Surgeons of Edinburgh. We trust that a full investigation will be made and prompt justice be administered.

#### SCHOOL-BOARD PLAYGROUNDS AND OPEN SPACES.

HER ROYAL HIGHNESS THE PRINCESS LOUISE, MARCHIONESS OF LORNE, has signified her willingness to become a patroness of the National Health Society, and his Grace the Duke of Westminster was elected President at the annual meeting of the Society, held on Monday last at its rooms in Berners Street. At the same time, a letter was read from the London School-Board, expressing the willingness of the Board to accede to the representations of the Society on the subject of utilising the playgrounds of the board-schools in London by fitting up eighteen selected playgrounds with suitable gymnastic apparatus, but stating that the Board would expect the Health Society to undertake the payment of caretakers, on the ground that it was proposed to admit not only the board-school children, but also other children, to the use of the playgrounds. The chairman, Mr. Ernest Hart, pointed out that the legal opinion on which this decision was avowedly based, was apparently given on insufficient grounds, and the matter was remitted to the Council for further action. The annual report of the Society was then adopted, and showed an extensive series of operations, by lectures to mothers' meetings and working-men's clubs, the circulation of tracts on health, papers and sanitary directions, the formation of park parties for poor children, etc. It was stated that the Society was prepared to organise sanitary teaching amongst the poor on a much more extended scale, on application from the clergy and others. A deputation was received from the Thirlmere Defence Association, who pointed out that the scheme for supplying Manchester with water from the Thirlmere lake was by no means the best alternative even from an administrative point of view, and was mainly a financial speculation, which ought to be opposed in its present form on the widest grounds of public health.

#### MEDICINE IN MONTENEGRO.

A LETTER from Dr. Studetzki, a Russian practitioner in Montenegro, recently published in the *St. Petersburg Medicinische Wochenschrift*, gives an account of the state of medicine in that principality. With the exception of the foreign (Russian) surgeons who have gone thither to render their services during the war, Montenegro has no scientifically educated practitioners. The whole of the medical practice is in the hands of a family named Jlitshkowsitch, whose scanty professional knowledge has been handed down from generation to generation. At the

present time, ten members of the family are engaged in the practice of surgery, which consists chiefly in the application of splints to fractures, frequent cauterisation of recent wounds with nitrate of silver, and drainage of gunshot wounds with tow. Their knowledge of anatomy is weak; and they dread hæmorrhages. The only operations which they perform are the extirpation of enlarged glands from the neck, extraction of foreign bodies, and trephining. This last operation is very frequently done; being regarded as necessary in almost every slight injury of the head. Sometimes, the head of the same individual is trephined in four or five places. The private surgeon of Prince Nicholas is a Frenchman; but he is not consulted by the people.

#### M. REGNAULT.

OUR Paris correspondent writes:—The death of M. Regnault has just taken place (January 21st), after a long and painful illness, in the sixty-eighth year of his age. M. Regnault was educated at the Polytechnic, which he left as civil engineer, and was attached to the mines, of which he rose to become the chief engineer in 1847. He was subsequently appointed Professor of General and Experimental Physics at the College of France, and of Chemistry at the Polytechnic. In 1830, he was elected Member of the Academy of Sciences, and in 1854 was appointed director of the manufactory at Sèvres. But it is as physicist he principally distinguished himself; and to him is due the determination of the numerical elements which enter into the calculation of the effects of heat and compression on the gases and elastic fluids. M. Regnault was author of several elementary works on chemistry and physics, which have been translated into different languages. By a painful coincidence, the death of this eminent man took place on the anniversary of the death of his son, a celebrated painter, who was mortally wounded at Bazenville in the last Franco-German war.

#### THE SPREAD OF DISEASE BY BOOKS.

THE necessity, which we have often pointed out, of adopting measures to prevent the spread of contagion by the agency of books, has been recognised in Kansas. The directors of the public library there have warned the public of this danger, and advised that, in the event of any epidemic occurring in the town, people who may have borrowed books from the library should keep them until it has passed, and expose them to the open air. No further issue to the homes of the townsfolk of books will be allowed while any disease of an infectious character is prevalent. Although but small attention is generally paid to this subject, the means of procuring immunity from this danger are simple. The books borrowed for the amusement of a patient suffering from a contagious ailment may be rendered innocuous by exposure to a high temperature, or even to the open air if the complaint be mild in form. In the ordinary course, it is the reprehensible custom to return a book direct from the infected bed to the library, without a thought as to the large number of readers through whose hands it may pass.

#### POISONING BY METHYLATED SPIRIT.

DR. VIGER (*Annales Médicales de Caen*) states that he has seen two cases of this form of poisoning in confirmed drunkards. In the first case, a prisoner came to consult him complaining of violent pain in the head and stomach; shortly afterwards, he fell into a state of complete prostration, and died on the following night. Another inmate of the same prison showed at first nearly the same symptoms; he was perspiring, with a stupefied manner; the pupils were much dilated; and he soon fell into coma with complete insensibility. The next day he was attacked with violent delirium, which, however, speedily abated. The pupils were still dilated, and his sight was completely lost for the time. This state only improved very slowly, and twenty days afterwards sight had only partially been re-established. M. Viger found that these two patients had for a long time used methylated spirit, which they found in an unrectified state in the form of varnish in a cabinet-maker's shop belonging to the prison. They first precipitated the gum-lac by water,

and then drank the spirit. M. Viger comes to the conclusion that the symptoms observed in these conditions give warrant for classing methylated spirit among narcotics producing stupefaction and delirium, since dilatation of the pupil, sleep-stupor, as well as complete loss of vision, have been found. These well-defined properties may, perhaps, give a place to this form of alcohol in the list of therapeutic agents.

#### ADULTERATED GIN.

IN Bristol, following the example of the Metropolitan authorities, numerous prosecutions of publicans have taken place lately for adulterating gin. In cases where the gin was reduced by 35 and 38 per cent. of water respectively, the cases were dismissed, it being shown that that was the normal condition of the gin sold in Bristol; but a fine of five shillings and costs was inflicted on a publican whose gin was 46 under proof and contained a pungent vegetable substance resembling pepper. At Wells, in Somersetshire, a local innkeeper was last week fined £5 and costs for refusing to sell a pint of gin from a quantity he had on sale at his bar.

#### M. BECQUEREL.

OUR Paris correspondent writes:—Death has been very busy of late among the eminent men of France and other parts of Europe, most of whom, however, had lived to a good old age. I have now to record the death of M. Antoine César Becquerel, the eminent Professor of Physics at the Jardin des Plantes. M. Becquerel was born in 1788, at Chatillon on the Loing, in the department of the Loiret. He was first intended for the Engineers, and was educated at the Polytechnic, which he left in 1808 as an Engineer officer. He served in Spain under the orders of Marshal Suchet, and took part in the sieges of Tortosa, Tarragona, Sagonta, and Valencia. In 1814, after the French campaign, in which he also took part, he left the military service and devoted himself to scientific researches, which acquired for him a world-wide reputation. He applied himself particularly to the study of electricity, on which he had published several works. In 1829, he was elected Member of the Academy of Sciences; in 1837, he was appointed Professor of Physics at the Museum of Natural History; and, in 1874, the Academy of Sciences presented him with a medal to commemorate the fiftieth year of his membership. He was also awarded the Copley Medal of the Royal Society of London. M. Becquerel, who had received from the Emperor Napoleon's own hands, in 1812, the cross of the Legion of Honour, was, about fifteen years ago, promoted to the dignity of Commander in that Order. He leaves a son, who was his assistant, and will most probably be his successor, in the Chair of Physics at the Jardin des Plantes.

#### THE PUBLIC HEALTH.

DURING last week, 6,001 births and 4,251 deaths were registered in London and twenty-two other large towns of the United Kingdom. The natural increase of population was 1,750. The mortality from all causes was at the average rate of 26 deaths annually in every 1,000 persons living. The annual death-rate was 28 per 1,000 in Edinburgh, 29 in Glasgow, and 28 in Dublin. The annual rates of mortality per 1,000 last week, in the twenty English towns, ranged in order from the lowest, were as follow: Portsmouth, 19; Leicester, 19; Norwich, 20; Nottingham, 21; Hull, 22; Newcastle-upon-Tyne, 22; Wolverhampton, 22; Bristol, 23; Brighton, 23; Leeds, 23; Sheffield, 23; Oldham, 25; Bradford, 25; Sunderland, 26; Plymouth, 27; Birmingham, 27; Manchester, 28; Salford, 28; London, 28; and Liverpool, 28. Whooping-cough continues to show fatal prevalence in Plymouth and Birmingham. The fatal cases of small-pox in London rose to 51, and one death was also referred to this disease both in Manchester and Norwich, whereas not one was returned in any of the seventeen other towns. In London, 2,563 births and 1,903 deaths were registered. Allowing for increase of population, the births were 38 below, while the deaths exceeded by 215, the average numbers in the corresponding week of the last ten years. The annual death-rate

from all causes, which in the two previous weeks had been equal to 27.6 and 25.7 per 1,000, rose last week to 27.8, a higher rate than has prevailed in any week since the beginning of April last. The 1,903 deaths included 51 from small-pox, 77 from measles, 35 from scarlet fever, 5 from diphtheria, 94 from whooping cough, 21 from different forms of fever, and 8 from diarrhoea; thus to the seven principal diseases of the zymotic class 291 deaths were referred, against 292 and 299 in the two preceding weeks. Of the 51 fatal small-pox cases in the metropolis, 25 were certified as unvaccinated and 14 as vaccinated, while in the remaining 12 cases the medical certificates gave no information as to vaccination. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had declined at the beginning of October last to 137, has since steadily increased to 309, 374, 415, and 468 at the end of the last four weeks; 129 new cases were admitted during last week, against 129 and 124 in the two preceding weeks. The Ilighgate Small-pox Hospital contained 47 patients on Saturday last; at the end of the three preceding weeks, the numbers had been 26, 36, and 43. The deaths referred to diseases of the respiratory organs, which had been 535 and 464 in the two previous weeks, rose to 541 last week, and exceeded the corrected weekly average by 133; 364 resulted from bronchitis and 118 from pneumonia. The London Fever Hospital contained 70 patients on Saturday last, including 53 cases of scarlet fever, 9 of enteric fever, and 6 of measles. In Greater London, 3,065 births and 2,233 deaths were registered, equal to annual rates of 35.9 and 26.2 per 1,000 of the population.

#### CORONER'S COURT FOR THE CITY.

THE City Commissioners of Sewers have recently erected a commodious range of buildings in connection with the City mortuary in Golden Lane, Barbican, consisting of a handsome court-room, fitted with every convenience for coroner, jury, counsel, witnesses, and the public, a mortuary chapel, *post mortem* room, and retiring-room for consultation. On Tuesday, Mr. Payne, when presiding at an inquest, expressed the obligations he, the jury, and the public were under to the authorities for their public spirited conduct.

#### THE MEDICO-LEGAL LECTURES AT THE MORGUE.

THE first of these lectures was delivered at the Morgue, by M. Brouardel, on the 9th instant. M. Devergier, M. Tardieu, many house-surgeons, young medical men, and also many distinguished hospital surgeons, were amongst his audience. After having recommended to his pupils the most careful discretion regarding what they might see and hear in the course of these lectures, M. Brouardel explained his proposed programme, and said that the lectures would be especially practical. Those who attended them would be present at medico-legal investigations, take notes, and, in the interval between two lectures, would prepare medico-legal reports, in reply to questions proposed by the legal functionaries: which reports would subsequently be corrected, as a rule, and discussed.

#### HYDROPHOBIA.

AN application was made last week, in the County Magistrates' Court, Liverpool, by Inspector Johnston, for an order for the confinement of all dogs within the Kirkdale division of the county, owing to the prevalence of hydrophobia. He instanced several cases of hydrophobia arising from dog-bites recently. An order was granted, to be in force to the end of February.—Another death has occurred from hydrophobia near Tarporley, Cheshire, making the third in the same district within the space of three weeks.

#### WATER-SUPPLY OF THE METROPOLIS.

THE Subcommittee of Delegates from the local boards of London, appointed to take into consideration the proposals of the Metropolitan Board of Works in reference to the water-supply, have reported to the general body of delegates that, after considering the scheme, they strongly recommend united action on the part of the local authorities

in guarding the ratepayers against the expenditure of an immense sum without most carefully and jealously watching the progress of these measures, and further to impress upon the Board the fact that many members of the Metropolitan Board of Works were shareholders in the water companies; and although they do not infer that this circumstance would influence them in the performance of their public duties, yet the committee feel justified in adding that circumstance as another important reason for combined active vigilance.

## SCOTLAND.

A MAN was poisoned last week, at Penicuik, by saltpetre, a quantity of which he had swallowed in mistake for Epsom salts.

DURING the past year, 1,192 patients were received at the Glasgow Convalescent Home at Lenzie, being an increase of 47 over the numbers in 1876. The expenditure for the whole year amounted to only £1,900.

THE annual report of the Glasgow Lock Hospital states that, during the past year, 430 patients, who were in the hospital, on an average, twenty-eight days, had been dismissed cured, leaving 27 under treatment. Of these patients, 242 were admitted for the first time, 110 for the second, and the remainder had been in more than twice before.

ONE of the managers of the Edinburgh Royal Infirmary, Mr. W. Law, ex-Lord Provost of the City, fell down dead in the street, as he was leaving a meeting of the managers, on Monday, 14th ultimo. Mr. Law had taken a great and prominent interest in the new Infirmary, and had contributed £1,000 to the building-fund.

THE death-rate of Edinburgh still remains high. Of the 115 deaths which were registered last week, no fewer than 62 were due to diseases of the chest. The city otherwise is very healthy, no death from fever, small-pox, scarlet fever, or diphtheria having been recorded last week. The only deaths from zymotic causes were eight attributed to measles and two from whooping-cough. The death-rate was equal to an annual mortality of 28 per 1,000.

SOME months ago, the Secretary of the Edinburgh Royal Asylum sued a lady residing near Dunfermline for the sum of £3 13s. 8d., for the support of her husband in the Asylum, from July 1st till August 10th, 1877. Sheriff Lamond then decided that the defender was not liable at common law for the support of her husband as sued for. Last week, the case came before the Sheriff in a new form. The pursuer issued a summons for the recovery of the sum mentioned, with interest, against the lunatic and his wife, "as in possession of and as intermitter with the goods in communion", and also their eldest son as "one of the next of kin". The case was transferred from the Small-debt Court to the Ordinary roll, in consequence of the important legal points involved.

#### EDINBURGH UNIVERSITY COURT.

AT a meeting, held on Monday last, the following among other business was transacted. Dr. Alexander Keiller was appointed an additional Examiner in Midwifery, in succession to Dr. Angus Macdonald, whose term of office had expired. Dr. T. Lauder Brunton was appointed additional Examiner in Materia Medica, in succession to Professor T. R. Fraser. Mr. John Chiene was appointed additional Examiner in Anatomy for a further term of office. Dr. Thomas Keith was appointed Examiner in Clinical Surgery, in succession to Dr. Dunsmure. The additional Examiners in Botany, Medical Jurisprudence, Practice of Physic, Natural History, Pathology, Surgery, Clinical Medicine, and Institutes of Medicine were reappointed for the current year. It was reported that no appeals had been received in connection with the Register of the General Council for 1878. Intimation was received that the Secretary of State for India in Council had approved of a system,

proposed by the Senatus, for the supervision of selected candidates for the Civil Service of India, who might attend the University of Edinburgh. There were present at the meeting: Sir A. Grant, Lord Curriehill, the Lord Provost, Lord Young, and Professor Campbell Fraser.

#### A NICE CLIMATE.

THE rainfall at Portree, Skye, during 1877, was 93.26 inches. The least rainfall in any month occurred in April, viz., 1.77 inches. The heaviest was in November, 15.69 inches. On October 14th, 4.98 inches fell within twenty-four hours. Rain fell on two hundred and eighty-three days during the year.

#### A WARNING.

A PAINFUL case of suicide took place in a railway-carriage of the north-going train, at Blair Athole, on the 18th ultimo. The occupants of a second-class compartment were Mr. R. Young of Elgin and Dr. Mackay, his brother-in-law, both passengers from London. The former was believed to be under the charge of the latter. On arrival at the station, Mr. Young wished to alight, but Dr. Mackay pressed him to remain in the carriage. Annoyed at this, he drew a penknife from his pocket, and, seizing Dr. Mackay round the back with one hand, cut his own throat in a very determined manner with the other. Death resulted in a few minutes. The deceased was forty years of age.

#### SEWAGE OF GLASGOW.

AN interesting report of the Sewage Committee has recently been received by the Town Council of Glasgow. The report deals with the sewage carried in drains and sewers, the other questions being taken up by the Health Committee. The recommendations of the Sewage Committee were that the system of having water-closets in factories, jails, workhouses, etc., should be prohibited, and that water-closets in small houses should be discouraged. They further recommend that all drain-soil and waste-pipes from water-closets, sinks, and baths should be executed under public supervision. Some of the drains and sewers under the streets had been constructed one hundred years ago, when the proper manner of constructing them was unknown. The sewage leaked, and in a great many districts of Glasgow there were sewage marshes under houses, which were a fruitful source of disease and death. As regards sewage gas, it was pointed out that there were direct connections from the houses with the worst of the sewers in an enormous number of houses. For the remedying of this, the Committee recommend that all these should be done under the control of the Board of Works, as these connections were almost always imperfect. The report was referred to the Health Committee.

### IRELAND.

LAST week, a person named Hare died at Portadown at the advanced age of 108 years.

AT a late meeting of the Committee of the Rush and Lusk Dispensary District, Dr. Charles Fahie was appointed Medical Officer, in the vacancy caused by the decease of Dr. Mahony.

A CASE of small-pox died in Newtownards Workhouse, last week, and two other cases are at present under treatment. The disease has been traced to Belfast, where one of the patients had contracted it unloading a vessel.

MR. ALEXANDER DUKE, L.K.Q.C.P.I., has been appointed an Assistant-Physician to the Rotunda Lying-in Hospital, in room of Mr. W. H. Hart, M.B., resigned. Mr. Duke was formerly Assistant-Physician Accoucheur to Stevens's Hospital.

#### ZYMOTIC DISEASES IN BELFAST.

DURING the December quarter, fever caused 71 deaths, scarlet fever 43, diarrhoea 36, measles 31, whooping cough 6, and diphtheria 1; these 188 deaths being equal to an annual mortality of 4.1 per 1,000

of the population. The mortality from fever appears high, and at present the disease is somewhat on the increase, as, during the week ending the 12th instant, there were 103 cases of fever under treatment in the Union Workhouse Hospital, 33 cases having been admitted during the week.

#### AN INQUEST IN DUBLIN.

WE are requested to publish the following facts in correction of the account, which appeared in the JOURNAL of January 12th, of a recent inquest held in Dublin. The inquest in question was held by Dr. N. White of Dublin, a medical man of no little experience; and our informant states that the jury sworn was one of unusual intelligence and respectability. Several witnesses were examined, including Dr. Brady, who had been called immediately on the discovery of the accident, and whose evidence was by no means limited, as we were then informed, to what he knew of the previous health of the deceased. All the witnesses were examined in the presence of the solicitors of the accident assurance company with whom the deceased was insured, and the solicitors of the family. We are assured that the evidence of death from accident was most conclusive. Both the assurance company, through their Dublin agent and solicitors, and the family of the deceased, through their solicitors, left it to the coroner and jury to say (in order to clear up any doubt they might have as to whether death resulted from disease or accident) whether they considered it desirable to have a *post mortem* examination made. Having heard the evidence, the jury unanimously expressed it as their opinion that such examination was quite unnecessary, the evidence before them leaving no shadow of doubt on their minds. The solicitors for the assurance company did not then ask for a *post mortem* examination, which they would have obtained had they not been satisfied with the evidence. The medical officer of the company had passed the deceased as a good life two years prior to the accident.

#### A NEW HOSPITAL.

IT is announced that the late Mr. John Berry of Dublin has bequeathed a sum of £26,000 for the purpose of founding an hospital in or near the city of Dublin. The trustees named are: the Roman Catholic Archbishop of Dublin, Cardinal Cullen; David Sherlock, Esq., Q.C., Sergeant-at-Law, and M.P. for King's County; and Theobald Purcell, Esq., Q.C., a Protestant Barrister of high standing and a Chairman of Quarter Sessions. We are at present without full information as to the powers in the hands of the trustees, beyond the statement that the proposed hospital is to be for the benefit of the sick poor, without religious distinction. The existing hospitals in Dublin are believed, by many competent judges, to be already too numerous. In many cases, they are, from pecuniary reasons, unable to maintain occupied the full number of beds they are capable of accommodating. Under these circumstances, it would be a subject of regret if the trustees, in administering this generous bequest, considered it incumbent on them to add another to the already too numerous small general hospitals of the city.

#### THE SANITARY CONDITION OF CORK.

WE recently drew attention to the inquiry lately instituted by the Local Government Board in reference to the prevalence of fever in Cork, which, it was alleged, was due to the impurity of the water-supply. The Board last week forwarded their report to the Public Health Committee of the Corporation, founded on the evidence obtained at the inquiry held by Dr. McCabe. With reference to the water-supply, although a good deal of the sewage from Macroom and Ballincollig Barracks passes into the river Lee, yet the Inspector does not think this materially increases the number of typhoid fever cases, owing to the small number attacked compared with the population. He alludes to the filtering works which are being erected, but considers that the sanitary authorities should take additional precautions, with reference to the purity of the water, at a place higher up than that from which the water-supply is taken. From the report, it appears that there are

about 20,000 houses in Cork, of which about one-half do not possess ordinary sanitary arrangements, and about one-fourth do not even possess ashpits. Also the main sewers, which discharge into tidal waters, have no ventilation shafts, although twice daily they are filled by the tide, and the street gulleys are all trapped. Fifty-two acres, thickly populated, are liable to be flooded through the sewers and over the quay walls. Overcrowding is shown to prevail, as there are 1,700 houses in Cork let in tenements, and, in about 2,400 cases, whole families occupy one single room. From these facts, it is apparent that the sanitary condition of the town is in need of improvement; and the Local Government Board recommend the appointment of a medical superintendent officer of health, possessing a competent knowledge of public hygiene. This suggestion is a very proper one; and we trust that, under the new arrangement, the evils attendant on imperfect water-supply, overcrowding, defective sewerage, etc., will to a great extent be removed.

#### THE EXTENSION OF ZYMOTIC DISEASE.

DR. BROWN RIGG, Medical Officer of the Moira Dispensary at Lurgan, lately drew the attention of the Local Government Board to the effect that, in many instances, he was able to trace fever to infection, the parties attacked refusing to go to hospital. He requested advice in the matter, as he could not cope with an epidemic, should such break out in his district, unless supplied with extended powers for enforcing cleanliness of houses and the forcible removal of patients to hospital. The Board, in a recent communication to the guardians, referred to the laws which enabled any justice to issue an order for the removal of contagious cases forcibly to hospital; but, in the discussion which ensued, it appeared to be the opinion of the guardians that a magistrate would not be justified in making such an order; and the matter has been referred to the Moira Dispensary Committee for their consideration.

#### DR. HUDSON.

We are glad to announce that Dr. Hudson, the President of the Dublin Branch of the Association, has been appointed to the honourable post of Physician in Ordinary to the Queen in Ireland, vacant by the lamented death of his former colleague at the Meath Hospital, Dr. Stokes. On Dr. Stokes's resignation last year of his seat in the General Medical Council, Dr. Hudson was chosen by the Crown as his successor. His appointment to that position, as well as to the one he now shares with Sir Dominic Corrigan, is as satisfactory as it is deserved.

#### SMALL-POX.

THIS disease is still prevalent in Dublin. Some cases of a peculiarly bad purpuric type have been under treatment, during the week, in Cork Street Fever Hospital. As a commentary upon the fact we mentioned in the JOURNAL of the 12th instant, relative to the large number of unvaccinated children in the city, we see that three fatal cases of small-pox among young children, all unvaccinated, were reported during the last fortnight from one district in the city. Even the Public Health Committee of the Corporation seems to be getting alarmed; and, in view of the large number of cases of small-pox recently reported, have requested the Local Government Board for a return, showing the number of births for the year 1877 in the North and South Dublin urban districts, the number of children vaccinated, and the number of deaths of children aged one year and under, stating those which have died of small-pox in 1877. What use, if any, is intended to be made of this return, when it is received, remains to be seen.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

AT the last meeting of this Society, before the proceedings commenced, the Rev. Dr. Haughton, alluding to the loss the Society had sustained by the death of Dr. Stokes, said it would be a work of supererogation on his part to dilate on the well-known qualities of their deceased

friend. He wished only to move, formally, that the Secretary be requested to convey to the family of Dr. Stokes the following resolution: "The Pathological Society of Dublin desire to express the deep sympathy of the members of the Society with the family of their late distinguished fellow-member, Dr. William Stokes—Honorary Secretary and one of the founders of the Society—in their sad bereavement; and that they had endeavoured, very inadequately, to express that sympathy by adjourning their meeting of the 12th January, the next after his decease." The motion was seconded by Dr. Head, and agreed to unanimously.

#### KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

THE annual course of Scientific Lectures for 1878 will be delivered in the College Hall, at five o'clock P.M., on each Monday in the six weeks, commencing Monday, February 4th. The following are the lecturers selected by the College: Dr. Walter G. Smith, on February 4th and 11th, "The Principles of Electro Therapeutics"; Dr. J. M. Purser, on February 18th and 25th, "Researches in the Anatomy and Physiology of the Spinal Cord"; Dr. Thomas W. Grimshaw, on March 4th and 11th, "The Present State of our knowledge of the Intimate Pathology of Contagion, and its relation to the prevention and treatment of Zymotic Diseases". All Licentiates in Medicine of the College will be admitted free of charge. All registered practitioners, who are not Licentiates, will be admitted free of charge, on presenting their cards at the door. A limited number of Senior Students will be admitted by admission cards, to be had of the Hospital Physicians.

#### POOR-LAW RELIEF IN IRELAND, 1877.

THE Local Government Board has recently issued a statement, which has been prepared in anticipation of more detailed information to be given in the next annual report, relative to indoor and outdoor relief during the year ended 29th September last, in comparison with that of the preceding year. From it we learn that the number of persons who received outdoor relief amounted to 72,000, being an increase of 5,884; and indoor relief to 195,000, exceeding the previous year by 11,679. The total poor relief expenditure came to £796,333, or an increase of £33,178 over 1876; whilst the expenses under the Medical Charities and Vaccination Acts cost £141,157, or a decrease of £306, the numbers so relieved being estimated at about 770,000. An increase appears in the expenses under the Sanitary Acts of £5,800 beyond that of the previous twelve months.

#### HEALTH OF DUBLIN: QUARTERLY REPORT.

DURING the quarter ending December 29th, the number of births registered in Dublin amounted to 2,201, being equal to the annual ratio of 1 in 35.7, or 28.0 in every 1,000 of the population; and the deaths to 2,195, affording an annual ratio of 1 in 35.9, or 27.9 per 1,000. The average number for the fourth quarter of the previous ten years was 1,946; and omitting the deaths (66) of persons admitted into public institutions from localities outside the district, the rate for last quarter was 27.0 per 1,000. The deaths from zymotic diseases during the quarter numbered 430, or 19.6 per cent. of the total deaths, and equal to an annual rate of 5.6 per 1,000 of the population; the average number of deaths from these diseases in the fourth quarter of the previous ten years being 434. One hundred and forty-seven deaths, or more than one-third of the mortality from all zymotic diseases last quarter, resulted from measles and its complications, which proved fatal in 123 instances during the previous three months. Ten deaths from small-pox and one from chicken-pox were registered. Fever caused 56 deaths, whooping-cough 35, scarlet fever 33, diphtheria 13, croup 38, diarrhoea 32, dysentery 11, and erysipelas 6. One hundred and seventy-three children died from convulsions, being 46 over the average number for the corresponding quarter of the ten previous years. Bronchitis caused 365 deaths, pneumonia 89, and lung-disease unspecified 26; the deaths from diseases of the respiratory organs being beyond the average. To heart-disease 100 deaths were ascribed, apoplexy 36, paralysis 30,

jaundice 2, and liver-disease unspecified 32. Phthisis caused 217 deaths, mesenteric disease 38, hydrocephalus 50, scrofula 14, cancer 50, and gout 2.

### THE ANNUAL MEETING OF THE DUBLIN BRANCH.

OUR Dublin correspondent writes:—The arrangements for the first annual meeting and dinner of this Branch on Wednesday next, in the King and Queen's College of Physicians, are now complete. A large attendance of members and their friends, both lay and medical, is anticipated. The fact that Dr. Wilkinson of Manchester, the President of the Association, and Mr. Ernest Hart of London, have accepted official invitations to come over from England for the occasion, has given the warmest satisfaction to the Branch. Their doing so, at doubtless much personal inconvenience, will be received by its members as a testimony of the readiness and desire of representative members of the Association to strengthen the new and important bond which the Dublin Branch forms between the members of our profession in England and Ireland. The South of Ireland and the new North of Ireland Branches will also be represented on the occasion.

### THE UNIVERSITY OF OXFORD.

WE are happy to learn that a meeting of the medical graduates of Oxford is to be held to-day, to consider the questions which have been raised in the correspondence which has appeared in this JOURNAL under the head of "The Lost Medical School".

### THE UNIVERSITY OF LONDON.

BESIDES the business mentioned in the BRITISH MEDICAL JOURNAL of last week as transacted at the meeting of Convocation, held on the 25th instant, the following matters were also considered.

Dr. PYE-SMITH moved, and Mr. W. SHAEN seconded the resolution: "That the questions of other constitutional changes than those determined by the Draft Charter be adjourned until the next meeting of Convocation; and that the subject of such changes be referred to the early consideration of the Annual Committee." The resolution was carried unanimously.

Dr. WEYMOUTH, in introducing his resolution, "That this house desires respectfully to suggest to the Senate the desirableness of moderating the severity of the examination for the degree of Doctor of Literature", remarked that, since the institution of the degree fourteen years ago, nine candidates had presented themselves for examination, eight of whom had failed to attain the degree. The resolution was withdrawn.

Mr. T. TYLER moved, "That certain facts and correspondence which had passed between the Chairman of Convocation and himself, relative to the refusal of the chairman to call a special meeting of Convocation in November last, were worthy of the house". The resolution was negatived by a very large majority.

Dr. P. PURVIS moved, "That it is desirable to reconsider the standing orders, Nos. 30 to 32 inclusive, and that it be referred to the Annual Committee to suggest such alterations therein, so as to bring the method of taking the votes of members of Convocation on amendments in accordance with the practice generally adopted at the present day in all public meetings". This resolution was negatived by a large majority.

Dr. R. P. B. TAAFFE moved, "That it be an instruction to the Annual Committee to consider whether it is not desirable to include Sanitary Science among the branches for the degrees in science of this university". The proposition was carried with one dissentient.

Mr. J. H. TAYLOR moved, "That the Senate be requested to alter the time for holding the D.Sc. Examination to the Midsummer or the Christmas vacation, since the time now appointed (the first twenty-one days of June) is specially inconvenient to those engaged in tuition". This proposition was lost.

Mr. J. H. TAYLOR also moved "That it is desirable that the practice of inserting in school advertisements such entries as 'First B.A., First B.Sc.', to be formally disapproved by the university, as misleading to the general public". This proposition was not carried.

The meeting then adjourned at 9.30 p.m.

## CORRESPONDENCE.

### THE LOST MEDICAL SCHOOL.

SIR,—I am not sure whether I, for one, should have taken any part in the controversy raised by your correspondent "A Member of Convocation", had not your leading article of this week tended to place the question on its proper basis.

This is not a personal question. With respect to the two Oxford professors who are especially aimed at, no one who knows them can possibly forget the self-denying activity, on the one hand, the impartial public spirit, on the other hand, which they have always displayed. It is a matter for satisfaction that the personal merits and services of these gentlemen (whom I am proud to be permitted to call my friends and teachers) have met with so warm a recognition; and, in all that has been said by their grateful pupils, I beg cordially to concur.

But, in another sense, this is not a personal question. It is of extremely small moment to us whether your correspondent has expressed himself with good taste or good feeling. Let it be granted that his letter was personal, discourteous, and unfair; what has that to do with the question whether medical studies shall be encouraged at Oxford, or whether they shall be crushed? Again, unlike my friend Dr. Champneys, I am quite unable to penetrate the incognito of "A Member of Convocation"; but, even if I did know the authorship of the letters thus signed, I should not regard that fact as of any importance. The questions at issue are simply these. Is the present state of things at Oxford satisfactory? Can it be improved, and, if so, by what means?

I know nothing whatever of the beginnings of the present correspondence, and my only excuse for troubling you with a letter is, that I have taken an interest in the subject for some years; that, during a somewhat wide experience of University life as student, teacher, and examiner, I have always borne the Oxford problem in mind; and that this experience has led me to opinions fundamentally opposed to those which have guided the policy of the Oxford professors.

Will you permit me, in order to show that these views are not of recent date, to quote some paragraphs from a letter which I addressed to one of your medical contemporaries in a discussion on the same subject more than ten years ago?

"Oxford has no medical school, principally because it has not been thought advisable that there should be one. At the time of the Oxford Commission (of 1857), when wide changes were introduced in the University curriculum, the question was often raised whether the attempt should be made to revive the professional studies of law and medicine. In both cases, it was thought useless to interfere with the (supposed) natural process which had transferred these studies to London. The consequence has been that, though the arrangements for teaching physical science in Oxford are in some respects unequalled in England, they have not been adapted to the wants of medical students. To put the matter plainly, men cannot get on their Oxford lectures certificates which are satisfactory to the London boards, and it is understood that the University authorities (in science and medicine) do not wish it to be otherwise. . . .

"The questions at issue are really two:—1. Can you ever attract medical students to the University, unless you provide them with a medical education? 2. Is it really impossible to found in Oxford a medical school not unworthy of a great University? The first question must, I fear, be answered in the negative (for reasons which need not now be discussed). With regard to the second point, the obstacles to the establishment of a medical school in Oxford will be found, on examination, to reduce themselves to one; namely, that Oxford has only about thirty thousand inhabitants. But it is important to remember that the University of Würzburg, one of the most illustrious medical schools in Germany, is in a town of thirty-six thousand inhabitants; and that Halle, which has a great reputation in North Germany for its school of clinical medicine, is not much larger. Further, great medical books, such as Luschka's *Human Anatomy*, Niemeyer's *Text-book of Medicine*, and Henle's classical work on *Anatomy*, have been written in the insignificant towns of Tübingen and Göttingen. These facts are enough to show that good work, both in the science and teaching of medicine, may be done in small towns, and that, especially in the scientific branches, deficiency of material may be more than compensated by the resources of a great University. Now, it is fortunate that these branches are exactly those which come first in the medical programme, and it is not easy to see why a man should not spend some two years at least in serious medical study in such a place as Oxford. The resources of the University in the way of physics,

chemistry, and comparative anatomy are already superior to those of the London schools, and no great changes are needed to make them at least equal in anatomy and physiology. Will the active and liberal representatives of medical and scientific interests in Oxford consider the feasibility of systematising this instruction, so as to make it both formally and actually sufficient for the medical student? Whether it should be attempted also to teach the other branches of medical study would be a matter for subsequent consideration."

Since these lines were written, no change has been made. The study of human anatomy and physiology is not more systematised now than it was then; scarcely more so than when the new museum was opened to students nearly twenty years ago. A very few men have been permitted, by a special act of grace, to present themselves for the Primary Examination of the College without the usual certificates; but this cannot be regarded as a permanent settlement of the question. This question of certificates has been for years the great grievance of Oxford medical students, and so strongly has it been felt, that I believe nearly all who know the system by experience are anxious that human anatomy and physiology should be taught as completely as in the London schools, or as they have been taught of late years in the University of Cambridge.

I am myself convinced, not only that it is necessary, but that such a change involves others, for which all may not be prepared, but for which, nevertheless, a very good case can, on other grounds, be made out.

It seems to me, in the first place, very desirable, for the sake of the medical profession, that a larger proportion of its members should pass through the universities. Without laying too great weight on the much abused name of culture, it is surely an object worth aiming at that the various professions should have had a common education, and some common recollections of the most impressionable period of their lives. If a considerable number of medical practitioners throughout the country had this bond of union with the country gentlemen, the clergy and other professions, surely the legitimate influence of our profession would be considerably extended. This consideration has been felt, I know, rather strongly by many persons in the University, Conservatives not less than Liberals, and they would willingly assist, if they could see the way to do so.

Further, it is surely not unimportant as regards the science of medicine. We are always hearing of the need of endowments for promoting unremunerative science, and the British Medical Association has shown its appreciation of this need by annual grants. Moreover, we know in London that higher medical education suffers from the fact that (as is the case in no other European country) the whole cost has to be borne by the students themselves. We cry out for endowments, and neglect those which we have. Here is a capital producing some thousands a year, which is equitably the property of medical science. Is it not worth an effort to see that it is profitably employed? Perhaps, in an ideal state, things might be better managed. It might be better to carry all the endowments to London, and expunge the only name of medicine from the University calendar; but all our law and custom are against such a transplantation. The endowments must be used where they are; only let them not be diverted to other ends.

Even the interests of independent science, viz., biology, in whose name alone the discouragement of medical studies is defended, would really be served by the encouragement of these very studies. The experience of all Europe seems to show that it is premature to separate the study of biology from the schools of medicine. It is not that we expect anatomists and physiologists to be engaged in practice; science is becoming too complex for that; but it is only from students of medicine (with rare exceptions) that you can recruit your students and teachers of biology. A scientific man is none the worse for having to go through the drudgery of professional training; probably much the better; and it is a great advantage for one who devotes himself to sciences as a career to have some bread-winning profession to fall back upon, should fame and fortune not sufficiently reward his scientific labours. These considerations are, I know, strongly felt by some biological teachers out of Oxford.

This is not the place to dwell upon the bearings of such changes as affecting University education in general; but I believe an alliance of the University with medicine would be a gain to both sides. Medical studies would not interfere with liberal studies; why should they? On the other hand, certain special defects, which are, with some plausibility, attributed to Oxford men, might receive precisely the right kind of corrective. The tone of undergraduate life might gain in seriousness and common sense, without losing any other valuable quality.

Whether moved or not by such reasons as these, there is, as I have

said, a pretty general feeling among younger men that some extension is desirable; but opinions differ widely as to the amount. Some would wish to see only anatomy and physiology taught; others advocate a partial curriculum, such as would occupy about the first two years of medical study; and others would create, as has been lately proposed, a complete Faculty.

It appears to me impossible to stop short of the last proposal; but the question can only be discussed by examining the existing machinery and considering how it should be changed, and what results these changes would have.

The chief medical office in Oxford is, of course, the Regius Professorship of Medicine. The position of the Regius Professor is like that of a general without a staff. If he gave lectures on medicine, he would not have any auditors prepared by their preliminary training to understand him. You cannot give men, profitably, a course on medicine till they know something at least of anatomy, physiology, and materia medica.

The Linacre Professorship of Anatomy and Physiology is, in startling contrast to the last, overburdened with subjects, which would, in a well organised university system, be divided among at least four professors; viz.: 1. Zoology; 2. Comparative Anatomy; 3. Physiology, including Histology; 4. Human Anatomy. The professor has, in addition, the charge of a large museum, the care and enlargement of which occupy a great deal of time.

It is evident, then, that the duties of such a post are anything but a sinecure, and it is not surprising if even the immense energy of Professor Rolleston cannot do justice to so wide a field. If he devote most of his teaching to the first two subjects named, take up some branches of physiology, and allow the study of human anatomy to be carried on under his direction to a certain extent, he will be fully occupied. No one can doubt that the original mistake was in attempting to combine a multiplicity of subjects in a single Professorship. This might once be excused by the proverbial wisdom of cutting your coat according to your cloth, but the incongruity has become more glaring every year, and now that abundant cloth may be had if it be only called for loudly enough, probably no one will defend so preposterous an arrangement. What can be expected of the holder of such a chair as this is certainly not that he should do more than he does, but that he should actively and cordially co-operate in transferring some of his burdens to the shoulders of others. You seem to imply that the Linacre Professorship is a medical chair, and has duties to the medical profession as such. This may be the case, and doubtless it was so intended by the illustrious founder, but the duties are now limited by the new statute framed by the former Commission and accepted by the University. What the precise provisions of that statute are I cannot say, not having access to the original.

The existing arrangements for supplementing the Linacre chair must just be mentioned. There is a Hope Professorship for Invertebrate Zoology, but this was chiefly destined by its founder to promote the study of entomology, and cannot at present be taken into account as a part of the teaching power of the University. Physiology will, there is every reason to believe, be the subject of a new Professorship. It is only to be hoped that the Commissioners will see the necessity of providing such a Professor with adequate assistance and laboratory accommodation. The department of Experimental Physiology, which receives little attention from the Linacre Professor, is already taught in the laboratory of Magdalen College by Mr. Yule. The cabinet of physiological apparatus is only in its commencement, but is already quite in advance of anything belonging to the University, and the laboratory has received warm eulogisms from several English and continental Professors of Physiology. There is a fair number of pupils, and it is hoped the subject may in time receive due recognition in the University examinations. But this is not in any sense a medical appointment.

The Lee's Readership was meant undoubtedly to be a medical appointment, and before its present occupant no one but a medical graduate was ever elected, but the teaching of human anatomy was greatly interfered with by the Anatomy Act. It is greatly to be regretted that it was not devoted to human anatomy or physiology at its last vacancy, which would have relieved the Linacre Professorship of one of its subjects.

It is clear, then, that anatomy and physiology cannot be provided for except by the foundation of new chairs. With regard to anatomy, it may, perhaps, be a question whether a Lectureship paid directly by the University, and tenable for a period of five years at a time, would not be preferable to a Professorship for life on a subject so strictly limited and so liable to be treated in a spirit of pedantry.

Those who are willing to allow this measure of advance must inevitably go further. It is a wasteful expenditure of time for a medi-

cal student to give two years to anatomy and physiology without learning any other subjects at the same time. Materia medica and botany are absolutely necessary. Why should there not be a Professor of Materia Medica and Therapeutics? Considerable ingenuity would be required to show why materia medica at least could not be studied as well in Oxford as in London. Moreover, would not a Professor of Therapeutics and Materia Medica in Oxford supply that deficiency, which we are told every day is so much to be regretted, of competent investigators in a position to make original researches? Botany would, no doubt, be well looked-after by the present Professor, especially when he would have the stimulus of an adequate class.

While working at these subjects, it is not to be supposed that students have much time for clinical work. Nevertheless, it is highly desirable that they should not defer too long attending medical and surgical practice. This is a point on which there is, of course, difference of opinion, but it would be generally agreed that minor surgery at least can be profitably learnt in the first two years, and that surgery illustrates anatomy too well to be safely deferred till the study of anatomy is finished. We must, then, have a Professor of Surgery, and secure admission for his pupils to the practice of the Radcliffe Infirmary. This could no doubt be effected by such a compact as is usually made when a medical school and hospital are connected.

Were the system thus far complete, a class would be prepared for the Regius and Clinical Professor of Medicine. We should not then see the incongruity, now too frequent, of an Oxford man, comparatively mature in age, and desiring to take the position of a second or third year's man at a London hospital, yet far more ignorant of the most familiar details of medicine and surgery than the average first year's man.

The subjects now sketched out form a distinct group, and some who are in favour of this degree of change may think it undesirable to include any of the "later" subjects, such as midwifery, forensic medicine, pathology, state medicine. But a careful following out of the same principles would show that in many cases it would be highly desirable that there should be the opportunity of learning these subjects, and in all there would be the clear gain of placing competent men in positions of comparative leisure and scientific opportunities. The career of the late Dr. Parkes of Netley is an admissible instance of what might be achieved under such circumstances.

There would, of course, be no law compelling students to pass their whole time at Oxford, and their own interests, or the foresight of their friends, might be trusted to guard them against any possible disadvantage incurred by doing so. As a matter of fact, it is probable that most men would spend some years at a London hospital, even if Oxford offered them a complete medical course.

The one objection of most weight likely to be made is simply that founded upon the small size of the Radcliffe Infirmary. Not that it is really smaller than the hospitals which have supported flourishing schools, such as University College or King's College, or than the university hospitals in the smaller German towns; but it may be supposed that a little country hospital will have less grave and less varied examples of disease. To this the answer is simple enough. It is (clinically speaking) the school which makes the hospital, not the hospital the school. The Radcliffe Infirmary is or used to be too much under the tyranny of Governors' letters, and many cases were admitted which would hardly be received in one of the smaller London hospitals. But if it became a medical school, no one can doubt that the effort would be made to select cases more suitable for clinical teaching, and that, like all hospitals similarly situated, it would, by relieving more serious disease, discharge its functions with increased benefit to the city and county. Among the advantages of medical education in Oxford would be the wider utility (I do not say the greater efficiency within its present sphere) of the Radcliffe Infirmary.—I am, yours, etc.,

J. F. PAYNE, Fellow of Magdalen College, Oxford.

Wimpole Street, January 22nd.

#### SHALL OXFORD TEACH MEDICINE?

SIR,—I have assisted in building up two medical schools in London, that at St. Mary's Hospital and that at the Royal Free, and have also watched the demise of several strugglers; and I have found the utility and ultimate success of each of these institutions is closely proportioned to the excellence of its clinical teaching, and its popularity among students to the opportunities afforded them of bedside study. Without this, none can be even moderately prosperous. It is, therefore, not without serious alarm that I hear the idea broached of attempting to start a medical school at Oxford, with the Radcliffe Infirmary as its

basis of clinical instruction; for I say advisedly that I never saw a hospital containing the legal number of beds which supplies such scanty material for the purpose as this. When the examiners for the M.B. degree take up half a dozen candidates to be tested in the wards, it always has to be made a matter of prearrangement and forethought to get together suitable cases for the purpose. And it is several years since the performance of an autopsy by the candidate (which is on the programme) has been possible. In strong contrast, when examining for the University of Durham at the Newcastle Hospital, which exceeds Oxford in beds only by about one-fifth, I have found my choice actually embarrassed by the number of well marked examples of disease. The reason of the difference is not far to seek. Newcastle is the manufacturing and commercial centre of a neighbourhood teeming with a struggling superabundant population. Oxford is an agricultural city, affording a placid home to the University among green pastures, where, as far as the eye can reach as the railroad approaches it, the main object of life seems to be to produce as many head of beasts and as few of men as possible. Nobody is to blame; the Radcliffe Infirmary was intended to be, and is, a model of what a county hospital should be: admirably managed and officered, and quite large enough for the population; in fact, it is larger than a population of equal amount is considered to require in other counties; and the consequence is, that there is not a succession of typical cases, such as are absolutely essential to clinical teaching, especially at the earlier parts of a student's course in the wards. The beds are filled, indeed, but necessarily with obscure, chronic, and convalescent cases, who doubtless are proper objects for charity, but not useful for illustration. Advanced pupils may often with advantage puzzle out these enigmas, but to juniors they are insoluble.

On these grounds, it may be held for certain that Oxford never can be a complete medical school, and pretending to be so would be positively injurious to education by holding forth a bad model. This was not so obvious to our forefathers, and their liberality has, therefore, supplied the University with considerable funds for the foundation of a clinical school. Nevertheless, salaries and teachers will not make pupils, and these have not come, with the exception of a few local surgeons, apprentices in former times. Nor will they ever, so long as the metropolitan hospitals continue attractive. Can we expect to succeed in the face of giant rivals, where Harvey, Boyle, Willis, Aldrich, Lee, and Acland have failed with the coast comparatively clear? Surely, the University Commissioners would not advise us to persevere in the experiment. They know too well that those who have never made a mistake never grow wiser.

Is there no way of attaining by a *cypres* method what the benefactors you have mentioned had at heart, the promotion of clinical knowledge? The plan that commends itself most to my mind is the conversion of the Aldrichian and other clinical professorships into fellowships, to be allotted for short terms of years, but renewable at discretion, to carry out definite subjects of clinical research, to be reported on and made public from time to time. Residence would be needless, and there are numerous Oxford graduates on hospital staffs who would be eager for the task of adorning the University and themselves with conspicuous honours, without being out of the way of more permanently remunerative employment.

I am unwilling to protract this letter by discussing the use to be made of other professorships for medical education; but a very easy arrangement would enable human anatomy to be taken as an honour subject in the physical science schools. I think the present broad standard of teaching in physiology and chemistry should be maintained; for it is essential to the class of candidates who alone seek the Oxford degree. To lower it for those who are contented with more easily obtained diplomas would be ruinous.

As to the Regius Professorship, it is held, as a Crown appointment should be, not for the benefit of this or that privileged profession, but of all Her Majesty's subjects. The widest discretion must be allowed to the holder as to how he may best make it available to the country's advantage. The untiring activity of the present occupant, and the numerous objects which his tenancy of the post has enabled him to attain, and which he could not have attained unless so placed, may make us cautious of laying a helping hand upon the ark.

Excuse a remonstrance against your adoption from a correspondent of the term "Lost School". He must know very little of the history of Oxford to suppose the school ever advanced beyond conception.—I am, sir, yours faithfully,

THOMAS K. CHAMBERS,

Consulting Physician to St. Mary's Hospital.

London, January 21st, 1878.

SIR,—If the charges brought against Dr. Acland by a "Member of Convocation" are true, the Professor has virtually said "Here is a

medical school; come let us destroy it, and the emoluments shall be ours". But to suppose that Dr. Acland has laid himself out to pocket the stipend and convert his office into a sinecure, is too ridiculous to be seriously entertained even by the most cynical of your readers. I, therefore, hope that the Professor's liberality will allow him to reply to his anonymous assailant; for there is much room for explanation and reform, as the following facts will show.

Wishing to spend part of my student's life in Oxford, about two years ago I entered at the University. I then called on Dr. Acland, and told him that I wished to be admitted a student of the Radcliffe Infirmary. The Clinical Professor raised no objection to my studying at the Radcliffe Infirmary, but said that he had never given certificates of such study, and that he would give none to me. When I asked why, the Professor said that they did not undertake to give certificates, and that they would not do so at the Radcliffe Infirmary; but this seemed to me to be a repetition of his statement, rather than an explanation of it. Imagine the consternation that would be caused at Cambridge or Trinity College, Dublin, by a similar discouragement on the part of the Regius Professor of Physic from clinical study within the walls of his own hospital!

Thinking that, if Dr. Acland seriously doubted the competence of the staff to undertake clinical teaching, the Radcliffe Infirmary should no longer remain a hospital recognised by the College of Surgeons, I wrote to the Secretary in order that the Council of the College might strike it off the list, or take what other steps they might deem necessary.

However, I must refrain from further comment on the Professor's refusal to give me a certificate for any medical study I might pursue at his hospital, as the question is still *sub judice* at the College of Surgeons, and is now occupying the attention of the Court of Examiners at Lincoln's Inn Fields.

I may state that, subsequently to the Professor's refusal, during the Trinity term 1877, I worked in the surgical wards of the Radcliffe Infirmary (not, however, with the view of obtaining a certificate), and there seemed to me to be just as good opportunities for clinical work as in any other hospital of the same size.—I am, your obediently,

GLYNN WHITTLE, M.D.

Parliament Terrace, Liverpool, January 23rd, 1878.

### PHYSICIANS' FEES.

SIR,—It seems to me that there need not be any lengthy writing on this subject, as the remedy lies in a nutshell. Skilled labour and experience from long practice demand adequate reward, whether in trade or profession. An opinion from counsel at the top of his profession is not to be had under a sum three or four times that which a junior counsel would charge. Let, therefore, the heads of our profession boldly take the place which their professional brethren and the public already accord to them, and refuse to go anywhere for a less fee than, say, five or ten guineas. They would get all their money at less labour, and leave some still good fees for their juniors.

No patient who really desired a consultation with one of the leaders of the profession would mind the extra cost; and, as there are gradations of pockets among patients, so there should be variety in the scale of consultants' fees. No patient or practitioner will call in an ordinary consultant if, for the same fee, he can obtain the opinion of some great man.—Yours faithfully,  
M.D. Oxon.  
January 1878.

SIR,—I shall be glad if you will allow me to say a few words on this subject, now under discussion in your pages. To make my letter the clearer, I will ask to begin with a definition, and that of the word "consultation". I take a consultation, then, to be "the careful taking into consideration, by two or more members of our profession, of the case of some person, the subject of injury or disease". This consultation, again, may be demanded from various reasons; e.g., the gravity of the illness, the obscurity of the symptoms, the momentous interests involved, or the wish or caprice of the sick man.

Under any of these conditions, the professional persons concerned will most commonly be the usual medical attendant of the invalid and some one of equal or of higher professional standing; whether this conferring takes place in the patient's house or in the physician's room, whether it be conducted by personal interview or by careful correspondence between the experts engaged, are points quite immaterial to my argument. This, too, is or should be implied in the word consultation: that the past history shall be clearly stated by some one who has for himself observed the conditions of which he speaks; and that moot or doubtful points in the case shall be put forward for solution by

a second authority, whose acumen, intelligence, or work shall enable him to speak *ex cathedra* with the weight of a superior knowledge.

I would further advance that those only who adhere to such lines of daily work and procedure can properly be entitled to call themselves "consulting physicians and surgeons".

The unanimous voice of the medical profession testifies to the value of careful inquiries and comparisons so instituted and carried out; and there are but few in our ranks who have not at some time or other, for themselves or those dear to them, gladly asked for, and thankfully acknowledged, skilled help so rendered. It is not, therefore, so much to maintain that consultations have grown to be accepted as often most desirable, often absolutely necessary, and that, in some way or other, they must be provided for; in other words, for such legitimate professional work there is constant requirement, and, therefore, for men who deservedly hold high position, there is to their hands a continual and adequate source of income.

But the answer will at once be made, that this is far from being the case; that the work is not forthcoming to the extent named; and that the incomes are not so readily made, even by men of world-wide reputation. I am unwillingly compelled to believe that this is the case; but I do not hesitate to maintain that the fault lies with the profession, not with the public; and that the great leaders of the profession are the most to blame in the matter.

In only two special lines of work is the public asked for adequate remuneration by the profession; viz., in capital operations performed by leading surgeons, metropolitan or other, and in distant country journeys undertaken indifferently by physicians or surgeons of eminence. Let the reader contrast the sums paid, and not unwillingly, by sufferers in either of the above classes, with the honorarium of one or two guineas given as a matter of course for a consultation at the home consulting-room: those comparatively unfrequent, these of hourly occurrence.

It is not possible to justify the daily tacit consent to the same standard of value for a medical opinion, whether the dictum come from the physician grey with years and rich in clinical knowledge, or from the man but just a few years in practice and fresh from the benches of the senior's lecture-room. If the latter be worth but the guinea, on what ground of fair dealing can the public expect to have the ripe knowledge of the teacher for the same return?

Consulting practitioners far too commonly declare themselves the competitors, not the allies, the antagonists, not the helpers, of the general practitioner. Witness the mixed practice in which many engage themselves. Let the letter of your first correspondent F.R.C.P. give evidence on this point. "He sees in his daily work one patient with another practitioner; later on, he is summoned into the country, by himself, it would seem; for no mention is made of any consultation. In other cases, he attends alone, and the visits run on." What is this but to be the general, not certainly the consulting, practitioner?

Take, again, the waiting-room of any practitioner of high reputation: the large majority of his morning visitors will probably have come for "an opinion", and the data presented for his guidance are confessedly of the slenderest; for no accurate professional statement is, as a rule, forthcoming either in writing or by word of mouth. Contrast this hasty perfunctory "simulacrum" of a careful decision with the plan followed out a few hours later at the hospital visit, with the details gleaned by the clerk of history, examination, and symptoms, and then cease to wonder if some of the observant public stigmatise the former as a something little short of an absolute farce.

Yet, even more than this, the bulk of the profession do not favour consultations properly so called, but rather decry and shrink from them: the consequence of the attitude which many leading London practitioners take up towards their brethren: an attitude of cold neglect, if not (and this it often has been to my own knowledge) of active depreciation.

The remedy for this unsatisfactory state of things, unjust to the profession in that much good work is very poorly remunerated, unjust to the suffering public in that, as a rule, the possible perfection of accurate inquiry is far from being ensured, is, I venture to assert, not far to seek. It simply needs that the office-holders in our colleges, the presidents of medical societies, and the senior officers of our hospitals decline to take any other than consulting work properly so-called, or, in other words, that they do not see the patients, except when they are introduced by some other practitioner; that they accept nothing below a minimum fee for such services of five guineas for each consultation; and that they do not take patients under their own personal care.

The absolute daily work of such men would, to their great relief, diminish, while their incomes would as certainly increase; for they would at once enlist the active assistance of the mass of general practi-

tioners, and, by so doing, very much improve the status of the whole profession. Some such plan as this would at once give to our seniors their well earned positions without fear of the unseemly rivalry now existent, and would carry many contingent advantages in its train.

I recommend the suggestion to the notice of your readers.—I am, sir, your obedient servant,  
M.D., F.R.C.S.  
January 14th, 1878.

SIR,—Permit me to add a brief contribution to the presently debated question of the fees and position of consultants. As a rule, I object to the reopening of ugly wounds when once cicatrisation has begun, so that at present I would fain keep aloof from the introduction of personalities; yet, no explanation having been given by the gentleman referred to by your correspondent "Not a Court or Club Surgeon", in the JOURNAL for December 29th, we may be allowed to infer that none can be given. As I also know something of consulting practice in the North, I wish to further illustrate some of our northern customs. One leading consulting surgeon, to which position, from his years, large experience, and acknowledged ability, he is well entitled, also arrogates to himself the primary place as consultant in medical cases, or at least readily undertakes such duties when called on; he further attends midwifery, going, in some instances, into the country and staying at the patients' homes for some days, at a less fee than the local practitioner could afford to do, presumably to form connection with the families. He has on more than one occasion visited country families, although another medical man was in attendance and ignorant of his so doing; and, but lately, the following incident occurred, which may be given as a sample of consulting tactics. "A patient who, sent from the country to get advice from this said gentleman, had to stay a few days, very properly, till a just opinion was formed of the case; but he returned in a few weeks, to remain for some time under his care as an ordinary patient, and, on leaving, was directed to come back again to repeat the same plan of consultation after the lapse of a few weeks." How long this might have gone on it is impossible to say, had not the sense of the patient been acute enough to discover the peculiarity of this consultation system. Now, it seems to me that such conduct on the part of seniors of the profession does great injury to their own and their junior relationships with the public; it destroys professional confidence, and must necessarily weaken the faith reposed in the ordinary medical attendant. People are but too apt to take advantage of such disharmony, and, therefore, it is that they not only feel inclined to dispute the modest bill of the general practitioner, but demur to the higher scale of fee expected by consultants. In short, if consultants do not keep themselves purely as such, and abstain from grasping the just belongings of their less eminent brethren, they have themselves to blame for being ranked as no better than what they are: general practitioners. If the general practitioner have confidence that his patient will be returned unprejudiced into his hands, he will have more willingness to advise the consultation, which, under the too frequently abused system referred to, he is often justly anxious to avoid. If the consultant, on the other hand, behave honourably to his brethren, he will seldom find his pecuniary interests injured thereby; it will be for the advantage of his clients, as well as their usual attendants, that the recognised fee of one, two, or three guineas shall be forthcoming.

"By outward show let's not be cheated;  
An ass should like an ass be treated."

January 1878.

Yours obediently,

ABERDEENSHIRE.

#### EXTENSION IN HIP-JOINT DISEASE.

SIR,—I confess to having read with surprise Mr. Adams's statement in your number of January 5th, to the effect that the application of extension by means of a weight for the purpose of relieving the pain of hip-joint disease is the greatest discovery of modern times in the treatment of that affection, and that the originality of that discovery is claimed by Dr. Henry G. Davis of New York. I have used and seen used this method of treatment for, I should say, at least twenty-five years. I claim no originality in the method; for it was certainly used by my predecessor, at the Hospital for Sick Children, Mr. A'hol Johnstone; and, in Mr. Marsh's paper, to which Mr. Adams gives a reference, there is a quotation from Sir B. Brodie's first edition very clearly recommending it. The plan of tying the weight on by means of a stirrup of strapping is, I believe, an American idea. In Mr. Marsh's paper, it is attributed to Professor Pancoast. Whether this be so or no, I think I am justified in saying that it was in use long before the year 1855, which Mr. Adams fixes on as that of Dr. Davis's supposed discovery. But, though a convenient and very practical idea, this can hardly be called a great discovery. There is no question at all

that we now know the value of continuous extension much more clearly than our predecessors did; but this seems to me to be the consequence, not of any grand discovery by any individual, but of the continued use of a very easy method of extension, which, as far as I know, was first practised by Brodie, though very probably devised by some one else, and was probably suggested by the difficulty of applying and keeping applied the long splint in childhood. I may safely say that I never heard of Dr. Davis's name in connection with the matter.

With regard to the value of motion in combination with extension in the treatment of diseases of the joints, I should very much like, if possible, to obtain some trustworthy evidence. Sayre's splint, as it is called (though the invention of this also is claimed by Dr. Davis or some other American surgeon), has been known and used in this country for a great number of years. I think it must be over fifteen years since I first used it at the Hospital for Sick Children. Some years afterwards, when Dr. Sayre visited England, he spoke so confidently about the benefits of the apparatus, that it was much more extensively used, and, since that time, I believe, has been always procurable at the chief instrument-makers'. Yet I cannot meet with anyone who continues to use it. My own experience of it has been that, though it seems to answer at first, and often sufficiently for the purpose of a temporary display, so that a child who has been quite unable to move is thereby enabled to walk a few steps easily, yet afterwards it does harm by becoming displaced, and so allowing painful and injurious contact and movement of one bone on the other. I am speaking now, of course, of cases in which the disease is really in an active stage, and not of such as those of Mr. Adams's patient, who was free from pain before the instrument was applied. In a case recently under my care, I thought I could trace the exacerbation of the symptoms leading to abscess in the joint to the use of Sayre's splint. The fact is, that we want much more definite accounts of cases, extending over a considerable period of time, before we can say whether such treatment does harm or good, and whether it prevents or favours ankylosis.—I am, yours, etc.,  
T. HOLMES.

London, January 14th, 1878.

#### THE PREVENTION OF HYDROPHOBIA.

SIR,—Will you allow me to ask the attention of your readers to a suggestion, which has, I think, some practical bearing on the prevention of hydrophobia? Would it not be well, in crowded communities like ours, where dogs are but little needed for the chase, to compel, by law, the removal of the canine teeth? The small number of dogs in which these teeth are required for special purposes might be exempted. It is the formidable canine tooth which, in nine bites out of ten, does the damage; without it, few dogs would be able to bite through clothing, for instance, and, in their attacks on each other, they would probably usually fail to break the skin. There would be but little suffering involved in the extraction, and the dogs themselves would be great gainers, not only in the diminished risk of rabies, but also in that they would not inflict on each other nearly so much pain in their ordinary quarrels.—I am, sir, yours, etc.,  
JONATHAN HUTCHINSON.

15, Cavendish Square, W., January 22nd, 1878.

### ASSOCIATION INTELLIGENCE.

#### DUBLIN BRANCH.

The first annual meeting of this Branch will be held in the Hall of the King and Queen's College of Physicians, Kildare Street, on Wednesday, January 30th, at 4 P.M. The President, Dr. HUDSON, will deliver an address.

The annual dinner of the Branch will also take place at 7 P.M. the same evening, in the College.

GEORGE F. DUFFEY, M.D., *Honorary Secretary.*

30, Fitzwilliam Place, Dublin, January 8th, 1878.

#### BATH AND BRISTOL BRANCH.

The third ordinary meeting of the Branch will be held at the York House, Bath, on Wednesday evening, January 30th, at a quarter past Seven o'clock: H. MARSHALL, M.D., President.

The evening will be devoted to the discussion of Hospitalism, which will be opened by R. W. Tibbitts, M.B.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, December 31st, 1877.

## BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

A SPECIAL general meeting will be held in the Queen's College on Thursday, January 31st, 1878. The Chair will be taken at 4 o'clock P.M.

*Business.*—"To consider the position of the profession in reference to the establishment of Provident Dispensaries in Birmingham", and to adopt such resolutions on the subject as the meeting may deem advisable.

JAMES SAWYER, M.D.,  
EDWARD MALINS, M.D., } *Hon. Secretaries.*

Birmingham, January 24th, 1878.

## MEDICO-PARLIAMENTARY.

*HOUSE OF LORDS.*—Friday, January 18th, 1878.

*Intemperance.*—The Earl of CORK, in the absence of the Duke of Westminster, moved the appointment of a Select Committee for the purpose of inquiring into the prevalence of habits of intemperance, and into the manner in which those habits had been affected by recent legislation and other causes.

Monday, January 21st.

*Intemperance.*—The following peers were appointed as the Select Committee on intemperance: The Lord Archbishop of Canterbury, the Lord Archbishop of York, the Duke of Westminster, the Earl of Shaftesbury, the Earl of Belmore, the Earl of Onslow, the Earl of Morley, the Earl of Dudley, the Earl of Kimberley, the Earl of Aberdeen, the Earl of Donoughmore, the Lord Bishop of Peterborough, the Lord Bishop of Exeter, the Lord Bishop of Carlisle, Lord Heniker, Lord Penrhyn, Lord Aberdare, Lord Cottesloe.

## HOUSE OF COMMONS.

*NOTICES.*—The following notices have been given.

Colonel Beresford: To ask the Secretary of State for the Home Department whether he will use his influence to postpone the consideration of the Bill promoted by the Metropolitan Board of Works for the purchase of the Water Companies, at a cost of many millions sterling, until that Board have, in accordance with the spirit of his recent reply to the Board, taken the necessary steps to prevent the recurrence of floods on the Surrey side of the water.—(Monday, January 28th.)

Mr. Edward Howard: Select Committee to inquire into the supply of water to the manufacturing districts of Lancashire and the West of Yorkshire, and any deficiencies likely to arise therein; and whether it is necessary or expedient to resort to the Westmorland and Cumberland Lakes to make good any deficiencies in such supply; and, if so, to what extent, and under what conditions, such resort should be sanctioned.—(Tuesday, January 29th.)

*BILLS.*—The following Bills have been introduced during the past week.

To consolidate and amend the Law relating to Factories and Workshops; brought in by Mr. Secretary Cross and Sir H. Selwin-Ibbetson; to be read a second time on January 24th.

To amend the Medical Act (1858); brought in by Dr. Lush, Sir Trevor Lawrence, Mr. Samuda, and Mr. Ritchie.

To facilitate the Control and Cure of Habitual Drunkards; brought in by Dr. Cameron, Mr. Clare Read, Mr. Ashley, Sir H. Jackson, Mr. E. Jenkins, Mr. W. Holms, and Mr. R. Smyth; to be read a second time on July 3rd.

To amend the Public Health Act (1875); brought in by Mr. A. Brown, Dr. Playfair, Mr. Ryder, and Mr. J. C. Cowen; to be read a second time on January 31st.

To consolidate and amend the Acts relating to Public Health in Ireland; brought in by Sir M. Hicks-Beach and Mr. Attorney-General for Ireland.

To amend the Law relating to County Infirmarys and to the Relief of the Poor in Ireland; brought in by Mr. Meldon, Mr. Shaw, and Mr. Errington; to be read a second time on May 15th.

For the repeal of the Contagious Diseases Acts, 1864, 1866, and 1869; brought in by Sir Harcourt Johnstone, Mr. Stansfeld, Mr. Whitbread, and Mr. Mundella; to be read a second time on May 22nd.

To amend the Law relating to Public Baths and Washhouses; brought in by Mr. Forsyth, Sir T. Chambers, Mr. Ritchie, and Colonel Beresford; to be read a second time on January 30th.

To make provision for the purchase by the Metropolitan Board of Works of the undertakings of the several Water Companies supplying

Water to the Metropolis, etc.; brought in by Sir J. McGarel-Hogg, Sir A. Lusk, Mr. Grantham, and Mr. Rodwell; referred to Examiners of Petitions on Private Bills.

To amend the Law relating to the Qualifications required for holding certain Medical Appointments; brought in by Mr. Errington, Mr. J. Mailland, and Mr. Blennerhassett.

To make provision for the more effective prevention of Cruelty to Animals; to be read a second time on July 10th.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE Great Berkhamstead Guardians and Rural Sanitary Authority have received the sanction of the Local Government Board to their borrowing a further sum of £1975, making altogether £2400, the estimated cost of a site and building for an infirmary for infectious and contagious diseases.

### BROMYARD No. 1 DISTRICT.

WE have heard it said that some men are better than their creeds; but in some things, at least, our beliefs are better than our practice. We believe, or profess to believe, that our Acts of Parliament go forth clothed with authority; and that, as provided for by these Acts of Parliament, the districts of the Poor Law Medical Officers are such that they can be worked. But the case of No. 1 District, Bromyard Union, shows that the Act of Parliament on the subject of Poor Law Medical Districts is conveniently ignored. That district, it seems, has an area of 32,979 acres. Considerably more than double what the legislature thinks any man can reasonably be expected to work. Thus Parliament thinks, and has fixed the total acreage to be confided to the care of any one man, for medical purposes, at 15,000 acres; and that area, if fairly peopled, will tax the energies of any man to attend to properly. Yet here is a case in which the Board of Guardians of Bromyard thinks differently, and has given effect to its thinking by assigning as one medical district to one man considerably more than double that allowed by law. Can it really expect that it can be efficiently attended to? Meanwhile, we would suggest that the Local Government Board may fairly call upon it to show cause for its opinion; and, failing proper reason assigned, see that the law be carried out, and the district broken up into two, with a remainder of 2,979 acres towards the formation of a third. Then there might be some hope that the poor would be seen to. As it stands, these immense districts simply render Poor Law attendance a farce, because the distance to be traversed, over hilly roads, and often in bad weather, is prohibitory both of the pauper's sending and of the doctor's attending. In this particular district we think the poor are fortunate in having such an indefatigable medical attendant as Mr. Powell.

## MILITARY AND NAVAL MEDICAL SERVICES.

### THE ROYAL VICTORIA HOSPITAL AT NETLEY.

THE nomination of Colonel R. C. Stewart to be "Governor and Commandant of the Royal Victoria Hospital at Netley" was notified in the *Gazette* a few evenings ago. The appointment of an officer who was not long since adjutant-general of the Madras army to the command of a hospital seemed strange enough, on reading the announcement, and none the less so that the principal medical officer of the hospital, a surgeon-general, ranking as a major-general, and evidently a distinguished officer, as the decoration of the Bath has been conferred on him, might well seem to be the natural head of such an establishment, under the general officer commanding the district in which it is placed. The posting of combatant officers in local command of hospitals has the advantage of affording opportunities of patronage, and perhaps also of rendering a few additional commanding officers available in case of war for service of a more legitimate kind; but, after all, it seems a questionable mode of attaining such ends. Until, however, some reformer springs up who will undertake the laborious and unenviable task of mastering details of military economy, especially of studying the instances in which costly appointments exist for the sakes of the officers holding them, and not from any need of their employment, neither the numbers of such "fifth wheels," nor the money outlay for officering the army are likely to be much lessened.

## OBITUARY.

C. M. THOMPSON, M.R.C.S.Eng., SEVENOAKS.

WE have to record the death of one of our oldest members, Mr. C. M. Thompson, who died, after a few days illness, at his residence at Sevenoaks, on January 14th, at the advanced age of 81.

He was the youngest son of the Rev. M. Thompson, rector of Mistley, Essex; received a good education at Dedham School; was apprenticed to his brother, then a practitioner at Manningtree; entered at St. Bartholomew's in 1814, and in 1817 became M.R.C.S. and L.S.A. He shortly afterwards settled at Westerham, and for nearly fifty years did a considerable practice, retiring from active work at the age of 70, to devote the evening of his life chiefly to works of benevolence and public usefulness.

A man of quick and ready penetration, of great energy and activity; of perfect self-reliance and confidence, based on accurate knowledge; of warm sympathies and charitable disposition, he was eminently calculated to fill and uphold the position of a country doctor; and, outside his strictly professional duties, was a powerful influence in all good work in his neighbourhood.

Mr. Thompson was an active member of the Association, and filled the office of President of the South-Eastern Branch twenty years ago. He was a skilful surgeon, and an accomplished practitioner; ever ready to accept all new aids in the treatment of disease, and retaining those he found to be true. His long experience dies with him; his only published work being some few interesting cases in the medical journals. His good qualities were warmly appreciated by his neighbours, who presented him with a handsome testimonial on his retirement, and showed him respect and attachment by attending in large numbers at his funeral.

### JOHN LANG, M.D., SOUTHPORT.

DR. LANG, who was unfortunately killed by an explosion of gas at his residence in Southport on January 5th, was born at Accrington, where he received his early education. He afterwards entered at University College, London, where he filled the post of house-surgeon at the hospital. He became M.R.C.S. and L.S.A. in 1855, and took the degree of M.D. in 1864. After having qualified in London, he was for two years House Surgeon to the Manchester Infirmary. He then practised in Accrington for a few years with marked success; but, preferring a larger and more central field, he returned to Manchester, where he became surgeon to the Hospital for Sick Children; and for some years carried on a considerable practice. He removed to Southport ten years ago. Here he was appointed Honorary Medical Officer to the Convalescent Hospital and Sea Bathing Infirmary. He was chosen Medical Officer of Health for Birkdale, and was elected to a seat in the Town Council of Southport. He took an active interest in the improvement of the sanitary condition of Southport, and he had the satisfaction in time of seeing his views adopted.

Dr. Lang was a Vice-President of the Lancashire and Cheshire Branch of the British Medical Association, and took great interest in the meeting held last year in Manchester, and in the visit to Southport of a part of the members. He was interred in the family vault at St. James' Church, Accrington. The Mayor and Town Councillors of Southport, the members of the Birkdale Local Board, and many of his professional brethren and others attended the funeral, which was joined at Accrington by many old friends from a distance.

**NATIONAL HOSPITAL FOR CONSUMPTION.**—The annual meeting of the governors of this hospital was held on the 22nd instant, at the offices, 12, Pall Mall, under the presidency of Lieut.-Colonel Atherly. Letters were read from Viscount Eversley (the President), the Duke of Grafton, the Earl of Powis, etc., regretting their inability to attend. The report of the Board of Management stated that the institution, which is situated at Ventnor on account of the superior salubrity of its climate, having now been finally completed, the whole one hundred and two bedrooms were occupied by patients. The number of patients had greatly increased, the mortality being only five per cent. The sum of £9,256 : 19 : 10 had been received during the past year; and on the 31st of December last there remained only £103 : 16 : 4 in hand towards the present year's expenses, after allowing for liabilities due. The Earl of Carnarvon will take the chair at the biennial dinner to be held at Willis's Rooms on the 20th of February next; and the Board rely mainly on the subscriptions then received to maintain the institution, there being no endowment. Votes of thanks to the officers and to the chairman brought the proceedings to a close.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, January 17th, 1878.

Deakin, James, Sole, Manchester  
Lambert, John Speare, St. Leonard's Crescent, Exeter  
Pearce, John Puckey, Biscovy Par, Cornwall  
Thomas, David Edward, Cummman, Carmarthenshire

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the ordinary monthly examination meetings of the College, held on Tuesday, Wednesday, and Thursday, January 8th, 9th, and 10th, 1878, the following candidates were successful.—For the Licences to practise Medicine and Midwifery.

Aherne, John Leonard  
Armstrong, Henry  
Arthur, Thomas Francis  
Barker, Annie Reay  
MacLigan, Bartholomew  
Redmond, Joseph Michael  
Spewart, William Ribton

For the Licence to practise Medicine.

Owen, Richard Foster

Roe, Arthur Legge

For the Licence to practise Midwifery.

Woodroffe, John Fitzhenry

### MEDICAL VACANCIES.

THE following vacancies are announced:—  
**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.**—Assistant-Physician. Applications to be made on or before the 26th instant.

**DURHAM COUNTY HOSPITAL.**—House-Surgeon. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 26th instant.

**IPSWICH BOROUGH LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.

**KENT COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer and Dispenser. Salary, £165 per annum, with furnished apartments, milk, vegetables, washing, and attendance. Applications to be made on or before February 6th.

**LIMERICK UNION.**—Resident Medical Officer of the Workhouse. Salary, £200 a year, with apartments, rations, etc. Applications up to the 30th instant.

**LIVERPOOL ROYAL SOUTHERN HOSPITAL.**—Two Honorary Surgeons. Election in February. For particulars, apply to Honorary Treasurer.

**LOUGHBOROUGH DISPENSARY AND INFIRMARY.**—Resident House-Surgeon. Salary, 100 guineas per annum, with furnished rooms, fire, lighting, and attendance. Applications to be made on or before the 26th instant.

**NEWCASTLE-UPON-TYNE INFIRMARY.**—Senior House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications to be made on or before February 4th.

**QUEEN'S UNIVERSITY IN IRELAND.**—Examiners for 1878 in the following subjects, at the salaries stated. Medicine, £100; Surgery, £100; Midwifery, £75; Materia Medica, £75; Medical Jurisprudence, £75. Applications to be addressed to the Secretary, at Dublin Castle, up to the 15th February.

**RADCLIFFE INFIRMARY, Oxford.**—Surgeon. Applications to be made on or before the 20th instant.

**ROYAL FREE HOSPITAL, Gray's Inn Road.**—Two Junior Resident Medical Officers. Applications on or before the 30th instant.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

ABBOTT, C. E., M.R.C.S.E., appointed House-Surgeon to the Liverpool Infirmary for Children, *vice* R. Clapp, L.R.C.P., resigned.

BARR, James, M.B., appointed Assistant-Physician to the Stanley Hospital, Liverpool.

DAVIES, Hugh Walter, M.R.C.S.Eng., appointed Surgeon to the Memorial Hospital, Jarrow-on-Tyne.

LLOYD, Edward J., M.D., appointed Medical Officer to the Normal College, Bangor, *vice* Lewis Jones, L.R.C.P.Ed., deceased.

\*MURPHY, James, B.A., M.D., appointed to the Chair of Botany in Durham University College of Medicine, Newcastle-upon-Tyne.

\*STOWERS, James H., M.D., appointed Physician to the St. John's Hospital for Diseases of the Skin, Leicester Square.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

#### BIRTHS.

FOX.—On January 22nd, at Clarence Street, Victoria Park, Manchester, the wife of Dacre Fox, F.R.C.S.E., of a son.

HARVEY.—On January 21st, at South Petherton, Somerset, the wife of \*Walter A. Harvey, M.E., of a son.

#### DEATH.

DAWSON.—On January 21st, at Hunmanby, Henry Lawrie, infant son of \*Dr. Dawson, aged 3 months.

**VACCINATION.**—Mr. J. W. Harrison has received a grant of £100 : 12 for efficient vaccination in his district, No. 1, Ecclesall Union, Sheffield. This is the third gratuity which he has received.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY.** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Dr. Leared, "Death in Typhoid Fever averted by the free use of Stimulants"; Dr. Dowse, "On Hereditary Syphilis as it affects the Brain and Nervous System".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

## THE "MEDICAL DIGEST".

**DR. NEALE**, of 60, Boundary Road, St. John's Wood, the author of the *Medical Digest*, writes to say that he proposes to issue a list of errata with the last volume of the New Sydenham Society for 1877, so that all the members may be able to correct their own copies, and will be obliged for any notes which may be sent to him of such errors. The *Medical Digest* was compiled in the midst of busy practice in a distant colony, which certainly increases the merit of the author, and explains some of the deficiencies to which we pointed in our notice of the book.

**SIR**,—I beg to state, in answer to "Inquirer" in your last issue, that Mr. John Bowie, 98, Lauriston Place, prepares gentlemen for the examination of the College of Physicians, Edinburgh.—I am, sir, yours truly, L.R.C.P.E.

## MEDICAL ETIQUETTE.

**SIR**,—I am somewhat glad that we have made a step forward at last, and that Dr. Beresford has admitted that the radius was well and thoroughly united, and could not have been bent or in any way interfered with by his manipulation, and also that the ulna was uninjured opposite the fracture of the radius. Will he now go on, without introducing any further irrelevant matter, to describe what he found wrong about the arm, what he did to remedy it, and how he did it?

What Dr. Beresford says about my letters requires no answer from me: the letters are before the readers of the *JOURNAL*, and they will judge for themselves; but about the certificate which he mentions, and which was written by Mr. Wood, and signed by him and Messrs Harries and Davies a few days after the Shrewsbury examination, I will just say it was intended for the managers of the colliery and not for the profession, but that it shall be forthcoming in my final statement.

I am sorry, sir, that we have occupied so much time and space, but I hope Dr. Beresford will now make a plain statement as to what was done for the man Morris in the Oswestry Cottage Hospital, and say what he has to say about the arm, and then I will reply at once.—I am, sir, yours very obediently, W. H. BOX, Chirk, North Wales, January 20th, 1878.

## FILTERS.

**R**,—Would you kindly tell me the best description of filter to get for home use, just to filter a gallon or two of water daily—one easy to keep clean and in order?—am, your obedient servant, J. B. BROWNS.

\* \* Two very excellent filters are the Bischoff filter and the Silicated Carbon Filter.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the Post Office do not allow letters to be addressed to initials and directed to any Post Office in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a Post Office.

## DR. DRYSDALE AND THE POPULATION QUESTION.

WE deeply regret to see the reports of a meeting at Notting Hill, at which Dr. Drysdale addressed an assemblage of mixed constitution on the population question, in company with Mrs. Besant. During a speech of upwards of an hour, he urged the "limitation of families" as a method of restraint upon population. Such doctrines are contrary to the purity of thought and manliness of life which are the characteristics of this nation. Dr. Drysdale's doctrines are wholly discountenanced by the medical profession; and we only mention this painful subject in order to utter a protest, lest by passing over the public aberrations and the course which that sincere but misguided physician is pursuing in this matter, it should meet with anything else than general disapprobation. In expressing that disapproval, we believe we are expressing the almost unanimous opinion of the profession in this country. The promulgation of such doctrines is not only mischievous but degrading, and we earnestly hope that Dr. Drysdale will, in his future public course in this matter, be guided rather by what is unquestionably the general feeling of his profession than by his own mistaken impulse.

## DIPHTHERIA.

**SIR**,—In reply to Dr. Semple's letter in the *JOURNAL* of the 19th instant, I would say I believe that I clearly comprehend the views expressed by Dr. George Johnson and himself on the subject of diphtheria, membranous croup, and acute catarrhal laryngitis. In my communication in the *JOURNAL* of the 12th instant, the word "croup" referred to membranous croup; and in speaking of croup and diphtheria being the same, I meant that they had the same origin, and were the same disease, without reference to the part attacked. I would now ask your indulgence to enter into the subject a little more fully. A particular specific blood-poison, when introduced into the system, gives rise, among other symptoms, to the formation of a peculiar membranous product, generally situated on the tonsils or upper portions of the air-passages. Now, after some years of observation, I am inclined to think that this same blood-poison may affect the system and yet the membrane not be produced. I regard the blood-poison as the essence of the malady, and look upon the membrane as a product and a symptom, and, as such, subject to variations and modifications. During diphtheria epidemics, I have frequently observed that the appearances on the tonsils, etc., of persons members of the same household, and suffering from the complaint at the same time, have varied in every degree; some having perfectly formed pellicles, while others would have a few specks, or only have the parts covered with what is usually described as glairy mucus, but which, I think, may be allied in composition to the fibrin of which the membranes are formed, some circumstance preventing it from concreting. I have further observed that the pellicles often become detached at a very early period. Applying these considerations to the larynx and trachea, why may not diphtheria in these positions be subject to the modifications found in more visible parts? and how would it be possible to draw a distinction between such modified cases with a specific origin and cases of so-called acute catarrhal laryngitis, supposed to have been caused by cold? I am somewhat sceptical as to how far cold, *per se*, is liable to produce catarrhal symptoms, attended with fever. In places where there are cases of diphtheria, colds (as they are called) are apt to become epidemic; whereas, with a much lower temperature and no diphtheria, the general health may in all respects be good; and if certain atmospheric conditions favour the spread of disease-germs, it is probable that those of diphtheria would be no exception. The amount of mortality depends upon the conditions of exudation, and these again upon the systemic affection: the amount of mortality is therefore a secondary result, and hardly to be relied upon in making a differential diagnosis.—I am, etc.

Southam, February 21st, 1878.

WALTER LATTEY.

**SIR**,—Under this heading, Mr. Lattey kindly draws my attention to a point upon which I had not commented in the communication printed in the *JOURNAL* of the 5th instant. As I intended simply to record a method of treatment, the point raised as to the distinction between "simple acute" and "specific" inflammation of the larynx is obviously a side issue; at the same time, I am glad of an opportunity of stating my impression that diphtheria, croup, and catarrhal laryngitis cannot be considered manifestations of the same blood-poison. In only one of these (diphtheria) can there be said to exist any blood-poisoning beyond that due to impeded respiration. I am further of opinion that all blood-poisoning is a consequence, not a cause, of the intensity of an affection—as, for instance, in vaccinia, in puerperal septicæmia; and further still, in the acute specific contagious diseases—order, Miasmatici (Aitken)—such as small-pox, scarlatina, measles, and so forth.

To specialise and point out the distinction between simple acute inflammation of the larynx and trachea (laryngo-tracheitis, "croup") and "specific" inflammation of the same (diphtheria), I should say that the former tends to a mucopurulent, perhaps somewhat tenacious, secretion, whilst the latter is characterised by the formation of a distinct coherent membrane on the mucous membrane of air-passages, œsophagus, and so forth. This membrane is not always to be detected during life; and as the symptoms in both cases are somewhat the same (especially amongst children and in the early stages), a satisfactory diagnosis cannot in all cases be arrived at until some progress has been made in the disease. It is obvious, under these circumstances, that treatment applicable to the one is not necessarily equally efficacious with the other.—I am, sir, yours very truly, J. MACNELL.

Sheffield Road, Barnsley, Yorkshire, January 16th, 1878.

## SORE NIPPLES.

**SIR**,—A patient of mine, who suffered much after her last confinement from sore nipples, is anxious that the recurrence of her trouble shall be prevented. I shall feel obliged if any of your readers will suggest a good application to use now and during lactation. She is in her sixth month.—I am, etc., E. R. S.

**DR. THOMAS S. PORRY** (Chester).—Personally, we sympathise with our correspondent; but as the matter is one on which there exists a marked division of opinion, not unaccompanied by heated feeling, and as an official decision has been taken, it is better to avoid fruitless discussion.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### THE TITLE OF DOCTOR.

THE question raised by Mr. George Blackman has been so often, and for the last time quite recently, very fully discussed, that we can see no advantage in again raising it; as the answer must always be the same. There is no legal right for any one not possessing the diploma of M.D. to use the title of "Dr.": on the other hand, members and licentiates of the various colleges of physicians are very largely in the habit of doing so, and consider themselves entitled by courtesy to the appellation, on the strength of the fact that their diplomas describe them as physicians; and that in the dictionary definitions and in the ordinary parlance of society, not only are "physician" and "doctor" held to be equivalent descriptions, but the term "doctor" is applied to medical practitioners of all grades. The term "doctor," originally strictly indicative of an university degree, has at some remote period obtained an extended vernacular application, as if from the want of any other single word in the language to express the practitioner of medicine. The presence in the English language of some such word as the Saxon *leech* (which is now represented by *leech=kirundo*), the Danish *Læge*, or the German *Arzt*, would have saved much confusion.

#### DOCTORS OF PHYSIC AND PHYSICIANS.

THE following remarks, made more than a hundred years ago by a President of the London College of Physicians, will interest some of our readers. Boswell was engaged as advocate for a corporation which was being prosecuted by a physician because they had, in some public document, styled him "Doctor of Medicine" instead of "Physician." Boswell wished Dr. Johnson's opinion "whether Doctor of Medicine is not a legitimate title, and whether it may be considered as a disadvantageous distinction." Johnson replies under date February 7th, 1775: "I consulted this morning the President of the London College of Physicians, who says that with us 'Doctor of Physic' (we do not say 'Doctor of Medicine') is the highest title that a practitioner of physic can have; that 'Doctor' implies not only 'Physician,' but teacher of physic; that every 'Doctor' is legally a physician; but no man not a Doctor can practise physic but by licence particularly granted. The Doctorate is a licence itself."—*Boswell's Life of Johnson*.

#### MEDICAL FEES.

SIR—The subject of medical practitioners' fees being now upon the carpet of public opinion, I have deemed it necessary to submit to the profession, through the JOURNAL, the following points for ventilation, with the view of their being improved upon.

A. B. has been sent for to visit a patient eight miles distant from his residence during the day. Whilst A. B. is in the village, C. D., not feeling quite well, consults the former about himself, when he would not have sent for him, and A. B. charges both patients the full journey. I submit this to be unfair and unjust to both individuals, and were the separate charge taken into court, the plaintiff would be consulted. My practice is to charge only the actual party sending for me the journey, and all other patients on the spot, for services rendered or medicine supplied. This might be considered too liberal, and that I should rightly charge a small fee for my visit to all parties not fetching me. This plan applies also to any cases requiring my attendance without a messenger being specially despatched for me. Again, supposing that A. B. has to take a journey eight, ten, or fifteen miles distant, calling on his way, to or from, at several houses to see patients, he is not justified in charging every individual the fee for the full journey, but only a reasonable fee for his visit. My practice is only to charge a visit fee if taken one mile (not under) off my road, the same as at home under that distance during the day.

Perhaps your readers will favour me with their views upon the following scale of charges, which I always make. Day visit in my own village, *nil*; night visit in my own village, 5s.; one mile distant from my residence, 1s. 6d.; day visit; if exceeding one mile, and under three, 2s. 6d.; day visit; if three miles, or exceeding, day visit, 1s. per mile; double charges at night, not being less than 5s.; for labour cases, if engaged, one guinea; for labour cases, not engaged, two guineas; for *Miss* draughts, 1s. 6d.; *Siv* mixtures, 2s.; *Siv* mixtures, 2s. 6d.; *Siv* ditto, 3s.; for *Siv* mixtures, 4s. 6d.; for each powder, 6d.; for consulting with another practitioner about my patient, *nil*.

I am informed that if A. B. be fetched ten miles distant from his residence, to a village with a good road, thereto, his fee is one sovereign, whereas my fee to the same place is eight shillings for eight miles of travelling over bad mountainous and marshy ground by day. I think that some fair and reasonable scale of fees should be arranged immediately, either by the General Medical Council or by the British Medical Association, and that steps should be forthwith taken for their universal adoption by the profession, compulsorily or voluntarily. I also suggest that classes and examinations should be established for the purpose of studying professional etiquette for students, before receiving their qualifications to practise.—I remain, sir, yours faithfully,

Great House, Llanbister, January 14th, 1878.

T. J. EAMES BROWN.

#### THE TREATMENT OF SCURVY.

WITH reference to our article on the above subject on the 5th instant, Dr. W. H. Taylor (Anerley) writes to call attention to a paper of his, contributed to the *Lancet* in 1876, a reprint of which he has forwarded. It consists of an abstract of the observations of Mr. J. W. Taylor in the Arctic regions, at Evigtok, in Greenland, in 1854-5, and again at Exeter Sound in 1875-8. On both those occasions Mr. Taylor found fine oxalate of potassium, with a little free oxalic acid, made both a pleasant drink and an efficient antiscorbutic; and he further asserts that it was efficacious when lime-juice, pickles, preserved meat and vegetables, and whatever else may be included under the head of "other remedies," failed. Dr. Taylor, therefore, proposes to issue binoxalate of potassium with oxalic acid to the navy instead of lime-juice and preserved meat and vegetables. On this point we have to remark that the statements are much too vague to be accepted without more strict investigation, and that we should hesitate to believe that scurvy occurred where a "fair supply of preserved meat, vegetables, lime-juice, pickles, etc.," were given, and was then cured by means of binoxalate of potassium. The salts of oxalic acid are certainly known and admitted to be good antiscorbutics, but there is no proof that they are so much more so than lime-juice as to be effectual where the latter failed. It is one thing to say that lime-juice was supplied, but quite another to see that it was actually drunk by each individual. Dr. Taylor comes to the conclusion that albumen, in the form of white of egg, was also highly beneficial; but the only reference to it in his paper is a footnote, in which he states that: "Mr. J. W. Taylor found that, after eating eggs for a short time, the pliable nails [of the scorbutic pa-

tients] were soon restored to their natural tone, and other symptoms improved." This statement is most vague, for it gives no information as to the other articles taken at the same time; for if the men got binoxalate of potassium at the same time, how were they able to say that the albumen had any effect? It is such want of precision that renders so many so-called observations useless for instruction, or for the solution of any *quæstio vexata*. We also doubt very much if Dr. Taylor's plan of preserving white of egg in its original condition, by merely adding a little salt, would answer.

In conclusion, we may say that the paper proves nothing new, as the value of oxalates was already known; but one grave objection to their issue is their intensely poisonous character: an objection which does not hold good with citrates, tartrates, or the other remedies usually employed.

M. B. will find the information he seeks in Gant's and Norton's recent works.

#### A QUERY AS TO ITALIAN MEDICINE.

SIR,—I notice a very interesting letter in last Saturday's BRITISH MEDICAL JOURNAL from a correspondent at Rome respecting the case of the late King of Italy. Much prejudice prevails still amongst people who have travelled on the Continent against the professional ability of the Italian medical practitioner. This has not been removed, but rather increased, by the unfortunate result of Victor Emmanuel's illness, followed so rapidly by the premature and unexpected death of Sir William Stirling Maxwell, Bart., of Perthshire. He had gone to Italy for the winter on an antiquarian and literary investigation, was not in ill health when he left, and fell ill in Venice, where he was heard of last, and died within a fortnight of his arrival there, on January 16th last. I should be obliged, therefore, if means could be taken, through the extensive correspondence of your JOURNAL, to ascertain some medical particulars respecting the fatal case of this eminent Scotch historian and politician from any of the faculty at Venice. In the obituary notices in the Edinburgh papers on January 17th, it is stated he died from a fever, contracted in some of the canal-girt palaces of the old city; and it is supposed he had no English servant with him, and probably not the services of an English doctor.—I remain, yours sincerely,

W. T. BLACK.

Edinburgh, January 20th, 1878.

WE are indebted to correspondents for the following periodicals, containing news reports, and other matters of medical interest:—The Birmingham Daily Post; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Masbro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Richmond and Ripon Chronicle; The Cambridge Independent; The Madras Mail; The Ashton Reporter; Saunders' News Letter; etc.

\* \* \* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

#### COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. J. Burdon Sanderson, London; Mr. Jonathan Hutchinson, London; Dr. B. Foster, Birmingham; Mr. W. S. Savory, London; Dr. Collie, Homerton; Dr. J. E. Bradbury, Cambridge; Mr. Rushton Parker, Liverpool; Dr. J. Milner Fothergill, London; Dr. Sawyer, Birmingham; Mr. Tweedy, London; Dr. H. Macnaughton Jones, Cork; Mr. Berkeley Hill, London; Dr. Newman, Stamford; Dr. J. Braxton Hicks, London; Dr. Grimshaw, Dublin; Dr. Napier, Fraserburgh; Mr. T. Holmes, London; Mr. Lowndes, Liverpool; Dr. R. H. Semple, London; Dr. MacLagan, Dundee; Mr. F. Mason, London; Mr. Reginald Harrison, Liverpool; W.; Dr. H. Charlton Bastian, London; Mr. Balmain Squire, London; Mr. Grant, Birmingham; Mr. J. Farrar, Morecambe; Dr. Gardner, Glasgow; Mr. C. M. Johnson, Lancaster; Mr. C. R. Carpenter, Stockwell; Mr. C. W. Dawson, Humnaby; K.; Mr. W. H. Box, Chirk; Dr. Duffield, London; The Registrar-General of England; Dr. Edis, London; Mr. Pugin Thornton, London; Dr. James Russell, Birmingham; Mr. J. Knowsley Thornton, London; Mr. James Startin, London; Dr. Gray, Castlewellan; Mr. Thomas McLaughlin, Londonderry; Our Edinburgh Correspondent; Surgeon-Major Martin, Netley; Our Dublin Correspondent; Dr. Bourneville, Paris; Dr. Pye-Smith, London; Dr. Hughlings Jackson, London; Dr. T. Birt, Leamington; Mr. C. Hunter, Hastings; Dr. J. W. Hamill, Winchester; Mr. W. N. Edgehill, Manchester; Dr. J. Maunsell, Barnsley; Mr. G. F. Rossiter, Weston-super-Mare; Mr. T. J. Eames Brown, Llanbister; etc.

# CLINICAL LECTURE ON PHLEBITIS.

By WILLIAM S. SAVORY, F.R.S.,

Surgeon to St. Bartholomew's Hospital.

I HAVE chosen the subject of Phlebitis for consideration to-day, because of late there has been an unusual number of instructive examples of it in our wards, and because it is a disease on the nature and character of which wide difference of opinion—I may venture to say, even much confusion of thought—still prevails. It must be confessed, too, that many of its causes, and among these perhaps the chief, are still obscure or altogether in the dark.

I need not tell you that our views of the pathology of this affection have, within the last quarter of a century or so, undergone a radical change. The old distinction between adhesive and suppurative phlebitis is now no longer held. Adhesive phlebitis is no longer recognised, because it is now known that the inflamed vein is rendered solid, its channel is blocked up, not by the effusion of plastic lymph from its wall, but by a coagulation of the blood which it contains. There is thrombosis. Suppurative phlebitis, in the old sense, is now no longer recognised, because we know that the fluid substance found in some cases in the interior of the vessel is not pus, in the proper acceptation of the term, but blood-clot, which has softened and become fluid from degeneration: puriform, but not purulent. That pus, however, or a fluid which at least cannot be distinguished from pus, may occasionally be found in the interior of a vein, cannot be denied. The coats of a vein, with more or less of the surrounding tissue, may inflame and suppurate, the integrity of the coats of the vessel may be destroyed, and the canal and space around may form a common cavity filled with pus; or, a vein may be wounded or opened by ulceration, and then some pus may enter from the outside. But, of course, events like this are not to be confounded with the old doctrine of suppurative phlebitis. The former of the two cases just mentioned is, of course, truly one of suppurative phlebitis; but, nevertheless, it is not the formation of pus in the canal by suppurative of its lining membrane. Yet here I cannot refrain from pointing out to you an instance of the extreme value of clear and sound observation, even though the interpretation of the facts recorded be at fault. Read the lecture on Phlebitis in the earlier editions of Sir Thomas Watson's great work. Read it again carefully, for even now it will more than repay you. It is, indeed, a sketch of the affection from the old view, but, study it now, by the light of modern pathology, and see how true the master's hand has been to nature.

Then, in phlebitis there is inflammation of the coats of the vein; and this is associated with the coagulation of the blood in the canal: thrombosis. This clot may be disposed of in various ways, of which more anon. The inflammation of the walls of the vein may lead to thickening from lymph, or to suppuration more or less extensive between the coats, which may, and perhaps usually does, extend into the surrounding cellular tissue. Here is an example. William E., aged 44, stout and rather florid, a clerk in a newspaper office, was admitted into the hospital in the following circumstances. Twelve days previously, being, he believed, in perfect health, he tripped on a stone and twisted his right foot and leg. Two days afterwards, he felt a pricking pain in the thigh in the course of the saphena vein, and the next day there was a red and painful swelling in the upper part. On admission, there was considerable swelling, not well defined, for about six inches in the course of the vein at the upper part. It was firm, painful, very tender, and hot, with a blush on the surface. The foot and leg were œdematous. He declared that he felt well, and there was no rise of temperature or other sign of constitutional disturbance. But the local signs of inflammation and suppuration increased, and, on the fourth day, fluctuation to some extent being obvious, a free incision was made, and about two ounces of sanious pus evacuated. The portion of vein in the midst of this was to a great extent evidently destroyed. From this time, the swelling and induration rapidly subsided. The wound continued to discharge pus, which soon became quite healthy, for about a fortnight. During this time, he made no complaint, but at the end of it he had a sudden and decided attack of gout in the foot, and he was in the hospital for another month. When he left, the vein could be traced, prominent and hard, from the wound down nearly to the knee; but, three or four weeks afterwards, it had become much less distinct.

First among the causes of phlebitis may be mentioned thrombosis;

and this at once opens the important question of the relation of thrombosis to phlebitis. As already mentioned, the two states are usually found together, and the thrombosis is regarded as included in, or a part of, the phlebitis; but let us ask whether thrombosis is always a part of phlebitis. Does phlebitis ever exist without any coagulation in the canal? If we turn to our museums, or to the records of examinations, I think we shall fail to obtain satisfactory evidence of the presence of actual phlebitis without any thrombosis. At all events, as a rule, veins which bear marks of inflammation contain fibrine; and the evidence thus obtained by dissection is borne out by clinical observation. I do not think there is good evidence of veins remaining free from plugging in the course of inflammation of their walls. Nay, there is for the most part very decided evidence that the canal is plugged. I say advisedly, in the course of inflammation; because, granted that thrombosis is associated with phlebitis, the further question comes: In what relation to each other do these states stand? Which is cause? which is effect? Or, more cautiously: If they are not invariably simultaneous at the outset, which of these two precedes the other? Are the signs of phlebitis ever present without any evidence of thrombosis? Rarely, I should say. More rarely, I venture to think, than is generally believed; but exceptionally, sometimes at the commencement, a superficial vein will exhibit plainly the signs of inflammation, and yet be comparatively soft and compressible, and admit apparently of being so emptied that it would seem as if it still contained nothing but fluid blood. Therefore, we may believe that phlebitis is sometimes a cause of thrombosis. Much more frequently the two conditions appear together. Thrombosis is found simultaneously with the evidence of inflammation of vein-walls. But, now, thrombosis may occur without phlebitis. This is undoubtedly far more common; and in such cases the thrombosis may or may not be followed by phlebitis. It is sometimes the apparent cause of phlebitis; but it sometimes exists for long periods without evidence, either during life or after death, of inflammation.

If, then, thrombosis is to be reckoned among the causes, and I should say it was one of the principal, of phlebitis, we ought next to inquire into the conditions under which thrombosis is likely to occur, that is, when it precedes or is not associated with phlebitis. And here it must be confessed that, in seeking any kind of answer to this question, we pass into a region of pathology singularly obscure.

In certain states of the constitution, or conditions of the system, thrombosis is likely to occur. We all know how the blood slowly coagulates in the great vessels after death, and that this change in some cases precedes death. It occurs during the act of dying, more especially perhaps when this process is prolonged or marked by extreme exhaustion, or when it forms the closing scene of long-continued and exhausting disease. And with reference to this, I may here remind you that much discussion has arisen on the question: whether clots, which are found in certain cases, have been formed during life or after death. The question is, after all, not a very profitable one; and it cannot, from the very nature of the case, admit of a definite answer. The process of dying is oftentimes very gradual. Molecular death is not synchronous with systemic death; and the coagulation of the blood, which is the visible sign of its dying, is in the body oftentimes a very ill-defined change. It is more satisfactory to inquire the age of blood-clots; whether these are quite recent, or bear evidence of change subsequent to their formation, in their degree of contraction, their dryness, density, and corrugation; in their colour and construction, whether laminated, or in minute structure fibrous; or—and this is usually most marked in the centre—showing signs of degeneration; or adherent to the lining membrane of the vessel which is more or less affected or destroyed. Only one word further with regard to their colour. These clots are generally described as becoming paler with age. But this holds good in one respect only. When clots are formed in the living vessels, and have at first the colour of the blood, undoubtedly, as time goes on, they gradually grow paler. The hæmature is absorbed, they come to consist of fibrine only, and this at length assumes a pale yellow or buff tint, and so it may remain. But we all know very well that, after death, clots are frequently found in the cavities of the heart and larger vessels, which are so soft and uniform that we have no doubt they have been rapidly and recently formed—little or no doubt that they have been formed after death—and which are, nevertheless, very much paler; in fact, almost white. Of course, the immediate explanation of this is obvious enough. It results from the mode of their formation, and the difference is due to the relation which the fibrine holds to the cells during its production. I need not dwell upon this any further.

But, again: "The great veins are very liable to become obstructed by clots forming in them when the patient is greatly debilitated, and when the circulation is enfeebled—by inflammatory affections, by discharging abscesses, difficult labours, and other causes." I have quoted

here from Professor Humphry's thesis, "On the Coagulation of the Blood in the Venous System during Life", which, although written now nearly twenty years ago, is yet so faithful an account of the affection that I can very strongly advise you to study it. It is singularly clear, considering the subject of which it treats, short but full, and requires very little addition, and still less correction, to bring it up to the present day. Yes. This thrombosis is an insidious affection, stealing upon convalescence from fevers or other exhausting diseases; and though but seldom directly destroying life, yet causing much tedious trouble, and sometimes permanently interfering with the free and full use of a limb.\*

In such cases, it would seem that the origin of the mischief is in the blood or its circulation; but still we must seek for an explanation of the fact that certain veins, those of the lower extremities, are far more liable to become plugged than others. And here, again, I cannot add anything worth your attention to what Professor Humphry has already set forth in the thesis referred to; and, therefore, to his pages I very gladly refer you. Note particularly his remarks on the arrangement of the veins, and on the structure of the internal surface of the popliteal.

But sometimes simple thrombosis appears to be determined by causes which are more purely local. Thus pressure on veins, producing obstruction of the circulation, may lead to the formation of clots.

For instance: a man about seventy, rather thin and vigorous for his years, had been laid up three months with simple transverse fracture of the patella, when, his health having been all the while good, the internal saphena vein of that limb, a few inches above the knee, became painful, tender, thickened, and solid. This was apparently due to slight pressure thereabout from the edge of a leathern splint which he wore. Some œdema of the limb soon followed. The trouble lasted some weeks, but did not extend, and his general health remained good, he throughout insisting that it was of no consequence.

So also, and with far more probability, will injury, such as laceration of the walls, or the presence of adjoining mischief. Thus inflammation or its products may coagulate the blood. But in the last case, the thrombosis is usually associated with and forms part of phlebitis; and to the causes of phlebitis I now return.

Phlebitis, then, may result from wounds of various kinds and other injuries of veins. But opinion on the liability of veins to inflame from traumatic causes, such as wounds, has been greatly modified in recent years. Formerly, wounds of veins were regarded with the utmost fear by the surgeon; for of all structures the veins were believed to be the most intolerant of injury, and it was only under pressure of most urgent need that a surgeon could be induced to apply a ligature to a bleeding vein—as, for instance, in an amputation. I remember when Mr. Skey stood, I think, alone among leading surgeons in exception to this view. But how remarkably has practice changed in this respect! Now-a-days, we very frequently see veins tied in various circumstances, and sometimes otherwise far more roughly treated, with comparatively little anxiety for the event; and it must be admitted that this confidence is largely justified by the experience of surgery. To what is this striking revolution in doctrine and practice due? Partly to extended observation, to deeper clinical experience, and partly to the advance of pathology, to the separation of simple thrombosis from phlebitis, and to the distinction drawn between them; and I believe also, though this is not acknowledged, to sounder and larger views of the pathology of pyæmia. On this point, however, I shall have something more to say presently.

Still, no doubt traumatic causes play a very important part in the production of phlebitis, and very often it is provoked by an extension of mischief in the neighbourhood of the larger veins, which become implicated. Take the following case. A spare active man, about forty-five, fond of and accustomed to what is called "free living", fell down on a skating-rink and struck his elbow violently. There was no fracture, but considerable bruising of the olecranon and adjacent parts. The arm was disabled for two or three weeks, and he went about during that time carrying it in a sling. I believe, however, that he submitted to no restraint so far as eating and drinking were concerned. A month after the injury, he came to me, complaining of more pain about the elbow, which now extended up the arm, and of the somewhat sudden accession of acute tenderness and considerable swelling. I found a line of tenderness, corresponding to the basilic vein, from the elbow to the middle of the arm; and here the vessel was unduly prominent and apparently plugged. With difficulty, I induced him to give heed to the mischief and to take more care. For some days, the symptoms, especially the swelling and tension, increased, suppuration seemed imminent, and I fancied that he felt more ill than he was willing to

admit; but there were no obvious signs of much constitutional disturbance, and never any œdema of the forearm. At length, but very slowly, the parts regained their normal condition, and even the vein itself ceased to be conspicuous.

Thus phlebitis may complicate gangrene, ulceration, erysipelas, and other affections, as in the following case. Elizabeth W., aged 38, was admitted into the hospital on March 27th, 1877. In the spring of 1876, this woman's descending colon was opened in the loin for intestinal obstruction, consequent on malignant disease of the uterus and rectum; and ever since the contents of the bowel had passed through the wound. More recently, she had been much troubled by prolapse of the colon, and the day before her admission it protruded to a far greater extent than ever. She had been unable to reduce it, and nothing had passed since. An everted portion of the colon, more than a foot in length, was outside. This was reduced under ether with considerable difficulty, and retained by a pad and bandage, which were removed daily to allow of defæcation. She was very weak, and occasionally suffered much from pain and sickness, which were relieved by opium. There was constant tendency to prolapse of the bowel. A month after admission, she complained of great pain in the left leg. It swelled rapidly, and the œdema soon reached the knee. The skin was pale. The superficial veins of the leg were distended and tortuous, and the internal saphena obviously plugged. There was great tenderness along its whole course. Temperature, 99.8 deg. A flannel bandage was applied. The limb remained in this state for a fortnight. Then the pain and distension slowly abated, and, three weeks from the commencement of the attack, she was tolerably comfortable, with some thickening only in the course of the saphena vein.

In this class may be reckoned that form of phlebitis which sometimes occurs after delivery: puerperal phlebitis. There is, indeed, much to account for thrombosis or phlebitis in the conditions which exist after parturition. A large surface of the uterus, left denuded by the separation of the placenta, and, opening freely upon this, large blood canals, which pass directly into veins. The formation in these of clot, as the inevitable consequence of the process; and, most perilous of all, the rapid changes of decomposition to which the fluids in the interior, and even in the walls, of the uterus are oftentimes liable.

Then there are causes of phlebitis which is more common in men than in women, that may be termed idiopathic. The rheumatic diathesis was formerly supposed to be a predisposing cause; but now, perhaps, for rheumatism we should substitute gout, and speak of the gouty diathesis as among the most prevalent of its causes. You all know what Sir James Paget has written on this subject—gouty phlebitis; and I shall not venture to add any touches to his picture.

Then phlebitis often exists in the course of blood-poisoning in its various forms. And much has been said and written, and great difference of opinion still prevails, on the relation which these affections hold to each other. For my own part, I believe that, when phlebitis is associated with blood-poisoning, in the majority of cases the phlebitis either intervenes as one of the local effects of the mischief, or, if it appear at the outset, it owes its origin to the same cause that produces the more universal disturbance. That, in such cases, phlebitis is the local and pyæmia the general effect of blood-poison. But, for the evidence upon which this opinion is founded, I must refer you to our hospital reports. Of the effects of phlebitis, I will speak presently.

Phlebitis is not common in childhood. It is not often seen so early as in the following case. Frederick V., aged 15, pale and delicate, a wine porter, complained of inability to flex fully his left knee and of pain in the ham. The saphena veins of both legs, chiefly at the outer and back part, were rather varicose. Those on the left side were especially filled and tender. The popliteal space was unnaturally full, tense, and tender on pressure. There was no œdema. He told us that the veins of the leg had always been conspicuous, but until recently had given him no trouble. Three or four weeks before admission, he fell when alighting from a train, and sprained his left leg; but of this he took no notice, and his present symptoms did not commence until a fortnight afterwards. There was no obvious disturbance of his health. By rest in bed for a few days, the fulness and tenderness in the ham abated, and then pressure detected a deep ill defined mass, which was believed to be the popliteal vein. About a week after his admission, the left calf became swollen and tender, and then a small, firm, very tender spot was discovered about the middle of the left leg, just behind the fibula, which was taken for a plugged vein. At this time, the temperature in the axilla was 99 deg.; pulse, 64 to 72. But no further mischief appeared. He generally complained, when asked, of aching pain either in the ham or calf, or both, but he could flex the leg much better. At the end of a fortnight, he left the hospital with the veins of both legs still varicose, but with no material tenderness in any portion of them. Ten days afterwards, however, he was readmitted with more

\* You will find a case of thrombosis, due to debility, without any previous definite disease, admirably described by Dr. Tuckwell in the *Medical Times and Gazette* of February 13th, 1864, p. 170.

fulness and tenderness in the left ham; and then the femoral vein in Scarpa's triangle was tender, prominent, and distinctly hard, and the change could be traced beyond Poupart's ligament. But there was very little oedema of the limb. He was kept at rest in bed. The mischief in the left limb gradually subsided; but, in the course of the third week, he complained of his right thigh, and the right femoral vein was found to be tender, swollen, and evidently plugged also, up to or even above Poupart's ligament; but no further mischief could be discovered in that limb. During the next week, he frequently complained of headache and heat, and his appetite failed, but there was no rise of pulse or of temperature. He was in the hospital nine weeks, during which time this evidence of fresh mischief slowly passed away; and, when he was discharged, hardly any abnormal condition could be discovered, either in the popliteal space or in Scarpa's triangle.

To what cause should the mischief be attributed in the following case? A young woman, aged 20, rather stout but of delicate aspect, was admitted into the hospital, complaining of much pain in the right leg. The whole limb was very slightly swollen, but the internal saphena vein stood out prominently, and could be distinctly traced with the eye almost from its commencement in front of the ankle to the middle of the thigh. To the touch, it was firm and cord-like throughout its entire course, and very tender. She told us that the limb had become painful a fortnight before her admission, and that the pain had gradually increased until she was hardly able to put her foot to the ground. Five months since, she was in the hospital suffering from the same affection of the same vein, with weakness and palpitation of the heart; but she recovered from this, the vein resuming its natural condition, and remained well until the present attack. Nothing amiss in the heart or elsewhere could be discovered. By rest in bed and warm fomentations the pain, which never appeared to be very severe, and tenderness gradually subsided, but the prominence and hardness of the vein remained. After being confined to bed for about three weeks, a bandage was applied to the limb, and she was allowed to sit up, and then to move about the ward. In another week, she was free from complaint, and able to walk without discomfort, but with a hard and prominent saphena vein. In the course of another week or two, however, before she was discharged, the vein apparently quite recovered its healthy state. Nothing unnatural could be detected by examination. During the time she was under observation, there was no perceptible derangement of her general health.

[To be continued.]

#### LOCALISATION IN SPINAL DISEASE:

ILLUSTRATED BY (1) A CASE OF "ATROPHIC PARALYSIS" IN AN ADULT; (2) A CASE OF CENTRAL MYELITIS;  
(3) A CASE OF ALCOHOLIC PARAPLEGIA\*

By JAMES RUSSELL, M.D.,  
Physician to the General Hospital, Birmingham.

THE two remaining cases are introduced for the contrast they present with the one just narrated. The loss of power and atrophy of muscular tissue in the patients were as pronounced as in the subject of the foregoing case; but, in addition, the function of sensation was seriously involved, indicating an extension of the morbid process to the region of the posterior horns. The two cases, though occurring from different causes, appear alike in their nature so far as the spinal symptoms were concerned. The second of the two is one of those melancholy instances described by Dr. Wilks (*Med. Times and Gaz.*, 1868, vol. ii, p. 470; and *Lancet*, 1872, vol. i, p. 320), and also referred to by Dr. Lockhart Clarke in the latter volume (p. 427), under the title of alcoholic paraplegia, which they have observed more particularly among females. On the Continent, Dr. Wilks ascribes the malady specially to imbibition of absinthe. In this form of paralysis, the lower extremities are especially liable to be affected, as is illustrated by my patient.

Both cases have much in common with the form of central myelitis described by M. Charcot, in which the entire grey tract is implicated, and the sensitive function which is related to the posterior horn suffers with the motor. The patients, however, were free from the more formidable phenomena of paralysis of the bladder and rectum, and the tendency to rapid production of sloughs, described by that observer as often connected with this particular disease. In the second case, the cerebral disorders of chronic alcoholism were added to the evidence of spinal disease. In the first case, the early symptoms undoubtedly point to the membranes as being affected at the outset, and probably

some of the pain complained of by the patient was due to irritation of the posterior nerve-roots. These pains in the limbs, especially in the region of the joints, which constituted a prominent subject of complaint in both of my patients, are noticed by Dr. Wilks. They have no small importance in reference to diagnosis, from the danger to which they give rise of the case being mistaken for rheumatism by a hasty observer. M. Charcot has, however, added fresh interest to the subject, in connection with the localisation of disease, by calling attention to the peculiar character which certain of these pains present, clearly observable in the first of my two patients; viz., that of their occurring in paroxysms, and presenting a peculiar lancinating character, recalling forcibly the distinctive nature of the pains of locomotor ataxy. From these considerations, M. Charcot suggests that the presence of pains answering to this description points to the probability of the disease having reached that district of the posterior columns in which certain fibres from the posterior root of the nerves pass to the grey matter. This region M. Charcot distinguishes by the designation "*la zone radicaire postérieure*". This zone is distinguished from the remaining portion of the posterior column (the column of Goll) by being developed at an earlier period, and is the seat, as M. Charcot demonstrates, of those changes which produce the phenomena of locomotor ataxy. It is worth adding that Dr. Wilks observes that the symptoms in alcoholic paraplegia are sometimes confined to the legs, and resemble in character the symptoms of locomotor ataxy.

CASE II.—A. R., aged 38. She presented a good family history. She had never been rheumatic. The account she gave of herself disclosed the fact that she had probably suffered in early life from an attack similar to her present one, but followed by a still more protracted recovery. She stated that, when seventeen years of age, she was in Gloucester Infirmary for nine months with symptoms like her present ones. She had severe pains in her limbs, and her legs wasted even more rapidly than they did on the present occasion. She was in bed for nine months, and even at the end of that time "had no use in her joints". She could raise her limbs in bed, but was unable to stand or walk, or even to feed herself. It was two years before her recovery was complete. She also had sharp pain in the occipital region and over the eyes, and could not see to read. She married when twenty-three years of age, and has had five children and two miscarriages. She is free from any evidence of syphilis. She is much employed in carrying heavy bundles of catalogues to and from the printer's, and is often wet through. She refers to one particular occasion, when she got her feet wet with snow-water. An attack of bronchitis was the consequence, for which she kept her bed for five weeks; and it was during the course of this illness that the first symptoms of her present complaint appeared, about four months before her admission into the Birmingham General Hospital. Her complaint began with pain of great severity, apparently meningeal, across the loins, reaching round the lower part of the abdomen and in the flank, which often prevented her from rising after having seated herself. Her appetite left her; but she was not aware of having had fever, though she was subject to attacks of burning heat, which came over her suddenly three or four times a day, accompanied by a sense of great weakness. Then came on severe pain in the feet and ankles; and afterwards she felt pain in the hands and arms and in the shoulder-blades. These pains were entirely without swelling; she describes them as being like cramps. They would attack her shoulders unawares, and shoot down the arms, so as to make her drop anything she had in her hand. She also spoke of formication in the soles of the feet and in the calves. She also had pain through the head from side to side, which caused her to forget everything for the time. She was treated for rheumatism; but in a month after the beginning of the illness she began to lose power in the legs, the feebleness steadily increasing. At the same time, "the flesh of her legs fell away rapidly". For the month preceding her admission into hospital, she was quite unable to walk, and for the last fortnight she kept her bed. The muscular atrophy increased with the paralysis; but in time her arms shared in the loss of power, and for a month before she came under my care she could not hold her needle in sewing. Her breath, too, became short, probably from deficient power in the inspiratory muscles. Whilst able to walk, want of breath often compelled her to stop. It does not appear that the sphincters were weakened. Whilst in the hospital, she complained of some urinary irritation, probably accounted for by descent of the uterus.

At admission, four months after the beginning of her complaint, she presented the appearance of a sound constitution, though she was thin. She had a remarkably apathetic melancholy manner. When talking, she often shed tears, and spoke in a very low tone. I may at once state that this peculiarity of manner was very prominent through the greater part of her illness, but underwent a striking change when improvement set in. She was unable to stand or to raise her feet from the

\* Concluded from page 122 of last number.

bed. Muscular power in the upper extremities was low. Both legs and thighs were greatly wasted, as will appear from the measurements to be given below. Faradic contractility was very low; in the arms, it was normal. The chest expanded less than three-quarters of an inch on forced inspiration. Sensibility in all its forms, including electro-sensibility, was greatly lowered in the lower extremities and abdominal parietes. It required a sharp thrust of the compasses to make their points felt; but the power of discriminating between heat and cold remained. Anæsthesia existed also in the upper extremities, but in a minor degree. The temperature in the axilla was normal. All her functions were performed naturally, excepting that menstruation had ceased since her illness began.

During the first six weeks of her residence, her symptoms showed no sign of improvement. The anæsthesia became more profound; muscular power still further lessened in the upper extremities, so that she could not retain anything long in her grasp without tremor in her arm and the certainty of dropping what she was holding. The deltoids also participated, and she could not raise her arms above the horizontal. Atrophy of the muscles increased, and the palmar eminences wasted, disclosing the metacarpal bone in the thenar eminences. Cutaneous sensibility was decidedly deadened in the fingers. She continued to make great complaint of darting pain in the blade-bones, shooting from shoulder to shoulder; and had constant paroxysms of pain starting from the fingers and darting to the wrists, leaving the hands numb. In addition, her feet and legs were numb, and she was kept awake by pains in the knees and ankles and up the leg-bones. She never presented any evidence of the exalted reflex irritability nor of the spasmodic movements of meningitis; nor was there any pain in the vertebral region. She was remarkably intolerant of the impression of cold, and "could bear any quantity of clothes". Her appetite continued defective, and her spirits depressed. Her bowels were costive.

The treatment had consisted of blisters on the spinal region; the full administration of iodide of potassium for some time, combined with the liquid extract of ergot; afterwards, of bichloride in small doses, which affected her gums. She was then placed on tincture of belladonna up to doses of twelve minims. At the end of the sixth week, the progress of the disease seemed checked. Improvement first showed itself by commencing return of sensation in the lower extremities. The various pains lessened in severity and became less frequent. Then the patient became able to grasp more steadily. Contemporaneously with these signs of amendment, the lower extremities became stronger; and in the tenth week of her residence in the hospital she was able to creep along, but it was not until the end of the third month that she could cross the ward on foot. With improvement in other respects, a marked change occurred in her general demeanour; she became cheerful, and her voice in talking lost its feebleness. The following observations on the girth of her limbs will illustrate the course of the malady through the muscular atrophy by which it was attended. The patient was admitted on February 17th. (The measurement of the thigh was taken seven inches above the patella.)

March 10th. Right thigh, 14½ inches; left thigh, 15 inches; right calf, 9 inches; left calf, 9½ inches.

April 16th. Right thigh, 12¾ inches; left thigh, 13½ inches; right calf, 8 inches; left calf, 8½ inches.

May 31st. Right thigh, 16 inches; left thigh, 16½ inches; right calf, 9¼ inches; left calf, 9½ inches.

August 2nd. Right thigh, 17½ inches; left thigh, 18 inches; right calf, 9¾ inches; left calf, 10¼ inches.

March 10th. Expansion of chest by forced inspiration, under three-quarters of an inch.

May 26th. Expansion of chest by forced inspiration, over an inch and a half.

During the course of her recovery, a fresh symptom appeared: paroxysms of profuse perspiration, soaking her clothes and pouring off her face. Some of these paroxysms lasted through a day or a night; otherwise for two or three hours. The nurse stated that she became scarlet all over when the perspiration occurred. The temperature of the axilla was from 98 to 97 deg. during the perspiration. On one occasion, the temperature of the hand was tested, and found to be 92 deg. As stated, she was admitted on February 17th. She left the hospital cured on September 1st.

CASE III.—The history of this case is, unfortunately, very defective, as my colleague in attendance had not seen the patient during the first part of her illness, and she had been removed from her own home. The patient had been addicted to habits of intemperance for an unknown period. She had certainly taken spirits; probably other liquids also. She had been compelled to keep her bed for a month on account of loss of power in the lower extremities. For how long power had been

failing, was not known. There was also an account of severe pain in the legs, and especially in the feet. At the time of my visit, her state of mental disorder prevented her from giving any clear account of her symptoms; but the nurse stated that she complained much of "chilblains" in her feet, and that she begged her to take off her boots, as they hurt her feet. There was also some indefinite account of pain in the lower part of the abdomen. When I saw her, there were much mental feebleness and some delusion; but, when her attention was roused in some special manner, she answered rationally for the moment, and obeyed directions with a fair degree of promptitude. When left to herself, she talked without reference to the reality of her position, and often tried to get out of bed. She had only sufficient power in her lower extremities to enable her to drag them about in bed. Muscular atrophy in the lower limbs was extreme. Sensation was so much impaired that a pin could be plunged deeply in the substance of the leg without eliciting any evidence of being felt. Her upper extremities were probably unaffected. She retained full control over the sphincters. Three days before my visit, her temperature was 104 deg.; it had declined to 100 deg. Her face had a healthy aspect; her appetite was good. There was no enlargement of the liver, and no albumen in the urine. The organs within the chest were healthy.

Two months after my visit, my friend writes me word that the patient remained with little change for five weeks. Her pulse averaged 110. Morning temperature was 100 deg.; evening, 102 deg. The temperature is now normal in the morning; 100 deg. in the evening. She was very talkative and excited, and manifested various delusions; she then became depressed, frequently crying. Her mind now is in a more healthy condition, though she never asks about her home. Sensation is restored in her legs; but atrophy of the muscles remains, and the flexor muscles appear to be acquiring preponderating power. She lies with her knees bent, and has pain in them. Her appetite has remained good; she has taken food well. Her bowels have been very costive. She has full power over her evacuations.

POSTSCRIPT.—I have had the opportunity of again seeing the patient the subject of Case I (page 121), three months after the last note of his case was taken. The condition of the limb has undergone no further change; but the young man now possesses some power of independent movement in the different segments of the lower extremity whilst walking. This statement confirms Meyer's observation that the disease in the adult disables less than in children.

## PHYSICIANS' PRESCRIPTIONS AND THE SALE OF POISONS ACT.

By JULIUS ALTHAUS, M.D.,

Physician to the Hospital for Epilepsy and Paralysis, Regent's Park.

AT the last meeting of the Clinical Society of London, I drew attention to a case of chorea, in which the patient had done himself a great deal of harm, and apparently killed himself, by the immoderate use of the hydrate of chloral, for which I had given him a single prescription in 1870, and which he continued, contrary to my advice, to take incessantly until his death in 1874. This case suggests an important question, which must, at various times, have occupied the professional mind; viz., whether the custom obtaining in this country, that patients may, at their own discretion and for years, procure from dispensing chemists any amount of certain powerful medicines, such as strychnia, opium, arsenic, etc., for which only one prescription has been given, is a proper one. In the case to which I allude, the patient had been in the habit of ordering wholesale supplies of the chloral mixture at a time from a leading West-End establishment, and showed me, at one of my visits, to my horror, a box full of twelve bottles of this medicine, which he had just received.

This custom, which has recently grown to excessive dimensions, is evidently a reprehensible one, inasmuch as it renders it impossible for the physician to regulate the dose which he wishes to be taken, and likewise opens the door to crime. Opium-eating and chloral-drinking may thus be readily induced, and a medicine which was intended to benefit becomes a curse to the patient. Again, secret poisoning, which remains undetected and unpunished, would appear to be by no means uncommon in this country, where the provisions of the Sale of Poisons Act are rendered to a great extent nugatory by the unlimited use which may be made of a formula, not only by the patient to whom it was originally given, but also by his friends, for whom, as is well known, the chemist frequently copies a prescription. Thus the would-be poisoner may go with a receipt for a small quantity of laudanum to twenty different chemists, put the supplies received together, and give the dose

to his intended victim. That this is no mere fancy picture, will be readily conceded by men of large experience in the profession.

I have taken some trouble to ascertain the custom which obtains in other countries in this respect, and have found that, with the only exception of Germany and Austria, complete liberty of the subject seems to exist everywhere as far as this point is concerned. In Holland and Belgium, there is no law restricting the chemist from again and again compounding the same prescription. Dr. J. Morel of Ghent tells me that, in Brussels and some other large towns, chemists' shops are hardly anything but magazines for the sale of patent medicines, which anybody may procure without trouble. In the smaller towns, there is less of this; but the doctors are in the habit of telling their patients to keep their prescriptions and have them made up again and again, if found useful. The consequence is, that the patient gains confidence in a prescription, instead of in the judgment of the doctor; he labels certain receipts as good for certain diseases or symptoms; thinks himself, after a time, perfectly able to judge as to what ought to be given in a special case, and, when a friend is ill, takes some formula out of his pocketbook and advises him to have it made up.

In Spain, patients can do exactly as they like. Dr. Jelly of Madrid says, however, that less mischief is done by Spaniards in this respect than by others, because Spanish doctors generally only write prescriptions for some simple infusions, or a small quantity of some advertised French nostrum, just sufficient to last for a day, and order their patients to come back to the doctor every day until they are cured. Dr. Jelly has, however, found many English travellers come to him with a pocketful of receipts from London physicians, and a plan of treatment laid down sufficient to last them a lifetime, and he thinks that the profession are as much to blame in the matter as the patients.

As for Italy, Dr. Eihardt of Rome tells me that prescriptions may be made up again and again without the sanction of the prescriber; but it sometimes occurs that, if they be very frequently asked for, the chemist will refuse to make them up again without receiving the doctor's assent. Italians, like Spaniards, take, as a rule, very little medicine, and Italian practitioners rarely order potent medicines, so that less harm is done in that country in this respect than elsewhere.

Dr. Frank of Cannes says that the same evil of which I complain here exists in France, and that he has no doubt that a great deal of harm is often done in consequence.

I understand from Dr. Marion Sims that, in the United States, there is absolute liberty to procure any quantities of powerful drugs from a single receipt, given perhaps many years ago, and that to his personal knowledge patients have ruined their health by the indiscriminate use of medicines at a time when these were no longer required.

Legislation on this subject exists, as far as I have been able to ascertain, only in Germany and Austria. Professor Westphal of Berlin says that, in Prussia, as long ago as 1801, a law was enacted requiring that all prescriptions written by either physicians or surgeons, and containing drastic purgatives, emetics, remedies used for bringing on menstruation and increasing urinary secretion, opiates and similar powerful drugs, shall, after having once been made up again, not be prepared a second time without the knowledge and approval of the prescriber, in consideration that such means may have been beneficial at the time they were ordered, while they might cause the death of a person at another time. As some inconvenience has arisen from too frequent applications to the prescriber for renewal, it has become of late years the custom in Germany for the prescriber, in case he thinks renewal desirable, to add the word *reiteretur* at once, and he may add to this the words *bis*, *ter*, etc., at his discretion. Unless this appear on the prescription, no good chemist will renew an old formula; and, if he did so, he would be punishable.

Professor Benedict of Vienna states that, in the Austrian pharmacopœia, the more powerful medicines, more especially the narcotics, ergotine, etc., are marked with a cross, and that the chemist is legally bound to give no more than one supply for a prescription containing any such drugs. Some physicians add at once the word *repetatur* or *bis*, *ter*, etc., where they consider it proper. All prescriptions have to be stamped by the chemist who makes them up, and who is also bound to put down the price he has charged for the medicine. Opium-eaters endeavour in all possible ways to circumvent this law; but the chemist who supplies them to excess lays himself open to an action at common law, and, where real harm has been done, even to criminal proceedings. Professor Benedict has mentioned to me, as an instance of the conscientious manner in which chemists in Austria generally discharge their functions, that, quite recently, when a physician, suffering from a painful affection, prescribed large doses of hydrate of chloral for himself, the chemist sent word back to say that he must request a prescription written by another doctor, as the prescriber might, under the influence of pain, take poisonous doses.

In talking this matter over with eminent members of the profession in London, I have been met with the reply that England is a country of free trade; that, when the patient has once given a fee for a prescription, it belongs to him; and that, in endeavouring to bring about a change, we should lay ourselves open to the suspicion of wishing to multiply our fees. Such objections, however, seem to me utterly untenable. Ours is not a trade, but a profession; there can be no earthly objection to a patient continuing as long as he likes the use of compound rhubarb pills or of simple tonics and alteratives, which, even when taken in excess, can produce no serious damage. As soon, however, as poisons come into play, the matter assumes an entirely different aspect, not only with regard to the individual, but also to the community. It seems to me the duty of the state to carry out the principle of the Sale of Poisons Act, not simply in the letter, but in the spirit; and to this end a legal check must be placed upon the indiscriminate supply of medicinal poisons. The public, if fairly reasoned with, must understand that it would be absurd to charge us with mercenary motives in such matters; and I have never experienced the slightest difficulty in convincing intelligent laymen, before whom I have occasionally laid this subject, that the change which I advocate is really desirable and proper.

It will be for the profession to give such an expression of their opinion on this matter as to induce the Royal College of Physicians, or the General Medical Council, to take action upon it in the proper quarter.

#### NOTES ON A CASE OF EMPYEMA FOLLOWING PLEUROPNEUMONIA IN A CHILD. TREATED BY INCISION AND DRAINAGE-TUBE.

By WILLIAM CAIRNS WICKS, M.B.Edin.,

Honorary Physician to the Newcastle-on-Tyne Dispensary; Assistant-Physician to the Newcastle Hospital for Sick Children.

E. J. M., A GIRL aged 7, came under observation on September 30th last, suffering from pleuropneumonia affecting the right side. She continued to progress satisfactorily till October 12th, when I found that she had passed a very restless night, and complained of pain in the affected side. On the 14th, a physical examination revealed the presence of an effusion in the right pleural cavity. On the 21st, as the fluid had accumulated in spite of ordinary treatment, I intimated the necessity for operative interference. The parents were not anxious that anything should be done, and it was with difficulty I got permission to operate on the following day if there should be no improvement. The right side measured nearly an inch and a half more than the left side. She had a distressing cough and great dyspnoea.

On the 22nd, I was called to see the child, as she was thought to be dying. She had had a "fainting fit", but was somewhat pallid when I arrived. The dyspnoea was urgent, and she was extremely weak. Some brandy was given, and I went for Mr. Angus, who kindly came to perform the necessary operation. The aspirator was used, the puncture being made in the seventh interspace in the infra-axillary region. About four ounces of thin inodorous pus escaped when the needle became occluded. A large one was carefully introduced; but in a short time the flow stopped, and it was completely blocked up by shreds of fibrine. Altogether about nine ounces of pus were evacuated; but, as the greater part still remained, we determined to make an incision and insert a drainage-tube.

On the 23rd, an incision was made, and about a pint of pus escaped, mingled with large shreds of fibrine. A drainage-tube was introduced, a pad of "tenax" applied, and over all a broad bandage.

October 24th. She had passed a good night. The discharge was free. The drainage-tube was removed, and the cavity syringed out with warm carbolic lotion (1 to 100); the punctures dressed as before.

October 25th. She was going on well. Pulse 100; temperature 98.8 deg.; respirations 34. Previously to the operation, the temperature was 103 deg., and the pulse varied from 120 to 130. The discharge was considerably less.

October 28th. Pulse 90; respirations 32. The cavity was washed out daily with warm carbolic lotion (now 1 to 80), and the drainage-tube gradually shortened. The discharge had almost entirely ceased. The appetite, which before the operation was lost, had daily improved, and she was now taking chop, beef-tea, milk, and eggs.

November 1st. There was no discharge on the dressings. The drainage-tube escaped from the pleural cavity, and the opening closed up (ninth day). The percussion-note was good anteriorly, and respiratory murmur was heard distinctly as low down as the wound anteriorly and posteriorly. There was evident flattening of the right side.

November 8th. The child had been up daily since the wound closed. The right side measured three-fourths of an inch less than the left. She was rapidly improving, and gaining in flesh and strength.

November 23rd. There was still a marked flattening of the right side. The percussion-note was good, and the respiratory murmur was heard as low down as the eighth rib anteriorly; but there were dulness and feeble breath-sound at the lower and posterior part. Her general health was good.

REMARKS.—In the above case, though carbolic lotion was used to wash out the cavity, no antiseptic spray was used at the time of operation, nor at any of the subsequent dressings. The patient is a strumous delicate child, with a bad family history; and the home surroundings were very unfavourable. The short time during which it was necessary to use the drainage-tube is also worthy of remark; the only similar instance I have noticed being recorded in the *Lancet* of December 6th, 1873, in which case it was removed on the ninth day. That case, however, had been treated antiseptically from the first. The treatment after operation consisted of quinine and tincture of iron, with a liberal diet; and, after the wound closed, of syrup of iodide of iron and cod-liver oil, with tincture of iodine externally.

Since writing the above, I have again seen the child, now eleven weeks after the operation. The area of dulness at the base of the lung is considerably less, and the respiratory murmur is more distinct. Her condition is most satisfactory, and the friends say "she never was so well in her life as she is at present".

### THE MARKET HARBOROUGH FASTING GIRL.

By FREDERICK GRANT, L.R.C.P., M.R.C.S., etc.,  
Market Harborough.

I SEND the following notes of this remarkable case, which has lately gone the round of the London and many of the country newspapers, as well as having been the subject of interest and curiosity to the neighbourhood for some years.

The patient, Martha White, who was the daughter of highly respectable working people in this town, had always been healthy, and was a good-looking fresh-coloured girl up to seventeen, who had menstruated pretty regularly for a year and a half. She first became ill in the early part of 1872, with symptoms of disturbed digestion, which soon subsided under treatment, when she complained of inability to swallow, which gained such ground that for a few days she took no food; but, on the stomach-pump being produced and its use threatened, she swallowed some liquid nourishment. This convinced the parents that the supposed inability arose from nervous disorder; and, no further indulgence in the idea being allowed or encouraged by them, she rapidly recovered, and returned to her work at a coffee-manufactory.

All went well till Whitsun week in 1873, when she was again ill with pain in the bowels and sickness, which were evidently principally, if not entirely, hysterical; but on this occasion moral force was futile, and all we could do was of no avail. After this had been going on for some weeks, I had the advantage of a consultation with Dr. Shaw of Leicester, who recommended the hypodermic injection of morphia and nutritive enemata, as the girl seemed sinking for want of food. At this time, she took nothing excepting butter-candy, of which she sucked nearly a pound daily. Even with this, her chosen diet, she was frequently sick.

This state of things continued until April 1874, when violent convulsions set in, the patient biting and hurting herself, and damaging the bedclothes and furniture. From this time, according to her friends, she took absolutely nothing, with the exception of one occasion, when I persuaded her to attempt to swallow a few drops of water in a teaspoon. She willingly tried; but, as soon as the food entered the pharynx, the most violent convulsions supervened, which continued throughout the day.

About the end of 1874, she became insensible and lost her sight. This continued for a year and a half, consciousness and sight returning at the same time, after a more than usually severe convulsion, which she described as excruciatingly painful. From this time, the convulsions occurred at regular intervals; namely, at 6.20, 6.50, 7.20, and 7.50 every evening, and continued in this succession until the day before her death (December 14th, 1877), when she complained of stiffness of the muscles of the face and constriction of the roof of the mouth and throat, dyspnoea increasing until she died.

At the *post mortem* examination, we found the body greatly emaciated and one mass of scars, produced by the continued injection of morphia; the legs tightly flexed on the hips, and the arms firmly crossed over the body. These required considerable force to displace

them, before we could make the necessary incisions. The stomach was very small and contracted, containing about half an ounce of dirty mucus. The oesophagus was small, but patent throughout. The bowels were natural, with slight congestion in some parts, probably *post mortem*. In the small intestine were from four to six ounces of the same material as contained in the stomach; and in the rectum a few small hard lumps of faeces, covered over with whitish mucus. The lungs were natural, as was the liver, which weighed forty-five ounces. The gall-bladder was full. The spleen weighed five ounces, and appeared healthy. The kidneys were congested, weighing three ounces and a half each. The urinary bladder was so completely atrophied as to be scarcely distinguishable, and was with great difficulty made out, even when aided by the ureter at one end and the blowpipe in the urethra at the other. The uterus was very small, and the ovaries very rudimentary. An examination of the brain and spinal cord was not permitted.

Throughout the whole of this long and troublesome case, there was no difficulty of diagnosis; for, although the disease simulated many disorders and implicated sooner or later nearly all the organs of the body, there could be no doubt that it was hysteria and nothing else. The prolonged starvation is, of course, its singular point; and I must leave to others to decide whether it is possible for a person to be kept alive for a period of three years and a half by morphia alone. To me, I confess, it seems incredible. But, although I have visited her at all times of the day and night; my assistants, my former partner, and many medical friends, have also watched and examined the case; no one has been able to detect any imposture, or to discover how food was given; and, from the contracted state of the patient's limbs, it was impossible for her to have helped herself. Nor, since the time when the mother states the last secretion passed (twelve months ago), have I been able to detect signs or smells of urine or faeces about the bed and body-linen of the patient.

The mother is one of the most energetic, straightforward, and useful women in the place, and, when unencumbered by nursing, could add largely to the family income. This has, of course, all been lost by the illness. They have steadfastly refused to let the girl be seen, except by medical men; and, with the exception of a water-bed which was procured by subscription raised independently, I believe I may safely say they have not made a single penny by the case; and of course the expense even for morphia alone, to persons in their position, has been a very serious matter.

### ON THE ETIOLOGY OF AURAL EXOSTOSES: OSSEOUS TUMOUR FOLLOWING EXTRAC- TION OF POLYPUS.

By GEORGE P. FIELD, M.R.C.S., Aural Surgeon to St. Mary's Hospital; etc.

M. W., A LITTLE girl aged 3, was brought to the hospital on July 25th. Her mother stated that she had suffered from a severe attack of measles twelve months previously, and that she had since had an offensive discharge from the left ear. I had a few months since removed a polypus. About a fortnight ago, she noticed a hard substance in the ear, causing the child much uneasiness. When she came to the hospital, a small pedunculated osseous tumour about the size of a pea was discovered, almost filling up the meatus. This case well illustrates the etiology of aural exostoses, as seen by the light which modern pathology has thrown upon inflammation of bone and resulting new growths of this tissue, and which Dr. Cassells has recently very correctly described in the *BRITISH MEDICAL JOURNAL* for December 15th, 1877. This, however, is only one form of the disease. Such tumours are frequently pedunculated, and might, indeed, be removed by the wire, as he has suggested. On the other hand, there is another and far more serious form of exostosis of ivory consistency (still less frequently met with), partaking of the nature of a new growth, and quite independent of inflammatory changes. Such growths of bone in other parts of the body would be called hyperostoses, and as such I presume Dr. Cassells would class them. Their development is insidious, and they occur in apparently healthy organs. Their very existence is not suspected until the patient discovers that his hearing is rapidly failing him; while the absence of pain might lead him to regard it at first as a trivial matter. Such a case I have at present under my own care, in whom many hours of patient work with the American drill while the patient was under chloroform have been necessary to perforate the thick mass of ivory-like bone completely filling each external meatus. Indeed, had it not been for the kindness of Dr.

Athur Mathewson of Brooklyn, New York, who sent me his pamphlet suggesting this ingenious treatment some eighteen months ago, I should have been at a loss to know how to penetrate this most dense tissue of almost adamantine consistency.

## CLINICAL MEMORANDA.

### PUERPERAL SCARLATINA.

IN the JOURNAL of December 29th, 1877, Mr. Haines gives an account of a case of puerperal scarlatina, in which the usual eruption and sore-throat of this exanthem were well marked. The reason of my alluding to it is that, in a remark at the conclusion, he says: "It bears out the opinion of Drs. Snow Beck, Meadows, and others, 'that scarlatina does not change and produce only malignant puerperal fever, but that it retains its specific characters in the parturient woman'." Now I think, in all discussions, it is always of paramount importance that we should have a clear idea of the points on which disagreement arises. I am not aware (though in this point I am under correction) that any one has stated that scarlatina could *only* give rise to "malignant puerperal fever". Certainly no one whose opinion was worth receiving could say so, for his experience must have frequently shown a puerperal woman suffering from scarlatina expressing itself as usual. The question, as I comprehend it, is whether the rash and sore-throat of scarlatina can be so far suppressed in the puerperal person as to be not noticeable, or scarcely so. In the case cited by Mr. Haines, if we exclude the rash and sore-throat, the symptoms are like those of puerperal fever. Now, it is by no means very rare that, in non-puerperal persons, the specific symptoms of scarlatina are absent more or less altogether; so it is argued that there is no *a priori* reason to deny the possibility of such a suppression of the specific symptoms in a puerperal person. Others seem to think that the presence of the exanthem, although not producing the specific symptoms, yet produces a general depression of the conservative forces of the body; that it renders it more exposed to the inroads of septic matter, etc. To whichever opinion we incline, or, indeed, whether we hold the concurrence to be a mere coincidence, we want narration of cases where delivery has occurred in connection with scarlatina, and the exact account of the progress to recovery, or the contrary.

The following case will show the difficulty of ascertaining the exact influence at work. The child of a multipara in her seventh month of pregnancy was scalded severely, requiring much nursing, which its mother carried out. During its recovery, the father and another child were attacked with scarlatina, from which they recovered as usual. The child was, however, then taken with typhoid fever, and was convalescent, when the mother was suddenly delivered prematurely. It had been recommended by the medical attendant that she should go into another house; but she refused, saying she was never better in her life. Before she could be persuaded, she was delivered. Within eighteen hours afterwards, violent symptoms of acute pyæmia arose, and went on to a fatal termination with a rapidity seldom exceeded; large patches of erythema occurring on her legs, but no specific symptom besides.

J. BRAXTON HICKS, M.D., F.R.S.

### DIPHTHERIA.

THOSE who consider that croup is a local disease caused by exposure to cold, and that its diagnostic feature is the presence of false membranes in the larynx, which have formed upon an inflamed mucous membrane, should by this time have been able to bring forward cases in which the existence of such membranes had been verified during life or after death. Should undeniable proof be forthcoming that such membranes can exist, then let it be shown that their existence is unaccompanied by constitutional disturbance, as is stated to be the case in croup.

Without entering into the various points of clinical history which may or may not be present in diphtheria, I would suggest a method which, I think, if tried in a reasonable number of cases, would prove satisfactorily that the so-called "croup" cannot exist as a separate disease. The method I propose is that, in a case of croup, a small blister should be applied to some part of the body; for, should there be a deposit of false membrane on the raw surface of the blister, then no further proof would be wanted to show that the disease supposed to be distinct from diphtheria was one and the same disease. But, until a false membrane can be shown present in an inflamed larynx, it must, it seems to me, be granted that membranous croup is no other disease than diphtheria solely affecting the larynx; and therefore the

term "croup" had better be used only in its proper signification, viz., a symptom peculiar to some laryngeal diseases.

W. PUGIN THORNTON, Devonshire Street, Portland Place, W.

## THERAPEUTIC MEMORANDA.

### JABORANDI AND ITS ALKALOID PILOCARPINE IN HYDROPHOBIA.

IN the BRITISH MEDICAL JOURNAL of January 26th, there is an interesting therapeutic memorandum, by Dr. Louis Henry of Manchester, on pilocarpine, the alkaloid or the active principle of jaborandi, which, he says, was discovered by Merck, and named *pilocarpium muraticum*. Dr. Henry observes that this would be a more elegant and effective way of introducing the more active properties of jaborandi into the system than that proposed by me. He seems to have overlooked the following observation, which occurred towards the end of my communication in your issue of the 5th instant, suggesting jaborandi as a remedy in hydrophobia, viz.: "If the active principle could be obtained, it would be much more easily managed in the form of a concentrated solution for hypodermic injection." I was not then aware that the active alkaloid of jaborandi had been separated. Since then, however, I have had information from two separate sources on the subject. Mr. Gerrard of University College Hospital writes to inform me that he discovered the active principle of jaborandi in 1875, of which he has kindly sent me a specimen in the form of a nitrate of the alkaloid. This, he tells me, can be obtained either from Messrs. Morson and Co. of Southampton Row, or Messrs. Hopkin and Williams of Hatton Garden. Messrs. Savory and Moore also inform me that they have prepared discs of pilocarpine for hypodermic use; and, from the well-known reliability of their preparations in this form, I think nothing can be more convenient and trustworthy for use. The physiological analogies of rabies and hydrophobia point so strongly to jaborandi or its alkaloid pilocarpine as its antidote and remedy, that I again urge most strongly that it should be speedily put to the test. The patient cannot possibly have either his sufferings increased by the experiment, or his chances of recovery diminished, as no remedy or treatment yet employed has either gone far to alleviate, much less to cure, the symptoms of this terrible malady. The more reason, then, for extending our search, especially in the direction that apparently presents physiological indications for selection.

J. G. SINCLAIR COGILL, M.D., F.R.C.P.,

Physician Royal National Hospital, etc., Ventnor.

### EXTERNAL USE OF TINCTURE OF BELLADONNA IN NIGHT-SWEATING.

FOR some little time past, I have employed the common pharmacopœial tincture of belladonna for sponging the body in cases of phthisical and excessive sweating, and invariably with marked benefit. So far as my experience goes, I have found it very much better than anything else; if applied before a sweating comes on, it prevents it; if during the sweating, it almost immediately controls it. Two teaspoonfuls of the tincture mixed with an equal quantity of whiskey are quite sufficient (applied with the hand) to cover the whole body and produce the desired effect. I have adopted this method of treatment in my last cases of scarlet fever, which have all done well; but they have not been numerous enough to justify any definite opinion of the value of belladonna applied in this manner.

J. STUART NAIRNE, Surgeon, Glasgow.

### TREATMENT OF DELIRIUM TREMENS.

MY attention has been arrested by an account of the treatment of a case of delirium tremens in its early stage, reported on page 127 of the JOURNAL of January 26th. It is, I believe, a generally accepted fact that opiates in delirium tremens do more harm than good, except occasionally in very protracted cases; and even then, only the amount of a full dose should be given in the twenty-four hours.

In chloral-hydrate and capsicum, we have two powerful remedies. The latter I have used for more than twelve years with unvarying success; it has never failed, no matter how violent the patient may have been, and I have had a man under treatment who required six strong men to hold him in bed. After four doses of the capsicum (thirty grains every hour in bolus), he fell into a calm sleep, and awoke a rational being. This was an extreme case, but milder cases simply require smaller doses of the capsicum.

C. S. WILLS, Surgeon-Major, A.M.D., Chester.

## REPORTS OF MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN.

UNIVERSITY CLINIC, BERLIN.

CASE OF CARCINOMATOUS TUMOUR BETWEEN THE PHARYNX AND LARYNX.

(Under the care of Professor LANGENBECK.)

[Reported by BEDFORD FENWICK, M.B.]

The patient was a male about sixty years old. He had suffered from dysphagia, occasional dyspnoea, and hoarseness of voice, of some standing; the first being now chiefly complained of.

On examination, a soft tumour could be felt on the right side of the neck, at the level of the thyroid cartilage, and over the carotid, which communicated a slight heaving impulse to it. The laryngoscope showed that the parts above the vocal cords were inflamed, and the larynx slightly compressed. The epiglottis was healthy. A bougie could be passed down the oesophagus, but with some difficulty.

The patient was put under chloroform, but rapidly became asphyxiated; the pupils were widely dilated, and the face livid. He was restored by artificial respiration. Tracheotomy was performed, and a tampon cannula inserted. The head being now bent back, with the neck horizontal, an incision was made on the right side from a point level with the great cornu of the hyoid bone, and about  $1\frac{1}{2}$  to  $1\frac{3}{4}$  inches from the median line, extending downwards and slightly inwards for about 4 to  $4\frac{1}{4}$  inches. All the muscles which hindered rotation of the hyoid to the left were then cut through in turn, and numerous vessels were ligatured; and a tumour of cauliflower-like appearance was found between the pharynx and larynx. Professor von Langenbeck then removed it with its attachments (having rotated the larynx); viz., half of the cricoid cartilage, partly right, partly posterior; the right arytenoid cartilage; and nearly the whole of the right half of the thyroid, the first and last being ossified.

The tumour was flattened, nearly circular in form, two inches in diameter and rather more than half an inch thick, pale yellow in colour, with a flat toadstool-like pedicle. Microscopically, it was found to be carcinomatous.

The patient went on well for two days; then lung-mischief (pneumonia) appeared, and he sank rapidly, dying on January 13th. No necropsy could be obtained; but Professor Langenbeck attributed death to the retention in the bronchi of mucus, discharge, etc., which the patient had not the strength to expectorate.

REMARKS.—The operation, I believe I am correct in saying, is quite novel in conception. Its execution, though dangerous, was most safely performed. That it was most skillfully performed, it is unnecessary to say. We have, then, the after-danger, say, of accumulation in the bronchi, as in this case, setting up fatal pneumonia, to prevent. Could not this be done by the employment of artificial respiration, giving the patient thus the all-necessary power of expelling this accumulation, which he would not himself possess?

### CITY OF GLASGOW FEVER HOSPITAL.

CASE OF SCARLET FEVER, FOLLOWED BY RHEUMATISM AND URTICARIA.

(Under the care of JAMES W. ALLAN, M.B., Superintendent and Physician.)

JEANIE S., aged 18, was admitted April 6th, 1877. The patient stated that the first symptom was sore throat. The presence of scarlatina rash is noted in the ward journal. The spray was employed for the throat, and she had milk-diet and scarlatina mixture.

April 27th.—The patient was up for eight days; but, taking a sore throat, went back to bed. She had now an attack of rheumatism (sharp), affecting the knees and ankles. The shoulders, elbows, and wrists were free. The tongue was moist, with a light coloured fur. There were herpetic patches about the mouth. Pulse, 100. The pain in the joints came on suddenly on the previous day. The affected joints were wrapped in cotton-wadding, and half a drachm of compound jalap powder was given in gruel at once.

On April 28th, the powder had operated. The patient had had a restless night, and said that the joints were not better, but she did not

seem to be in such suffering as on the day before. She perspired during the night. She still had pain in the knees and ankles; these were the only joints affected. Desquamation was taking place on the hands. The joints were ordered to be kept wrapped in cotton wadding, and five grains of Dover's powder to be given every four hours. Milk-diet was ordered.

April 29th.—The pain was much less; in the feet it was gone; but she had an attack of urticaria; no itching. She had taken four of the powders altogether—three yesterday and one to-day.

The cases in this ward subsequently passed under the care of my friend Dr. Dunn, assistant medical officer, and he dismissed this patient well on May 30th.

## REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 25TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*A Case of Spina Bifida successfully treated by the Injection of Iodine.*

Mr. A. PEARCE GOULD read notes of this case. The patient was born with a tumour of the size of a hen's egg, situated over the last lumbar and the upper sacral vertebra; this slowly increased in size, whilst the skin over it thinned. When eighteen months old, he was brought to the Hospital for Sick Children. The tumour was then of the size of a cricket-ball, sessile, with all the usual characters of spina bifida; an opaque band was seen along the middle line of the lower three-fourths of the tumour. There was no paralysis or other deformity. The head was large; the fontanelle was widely open, becoming bulged when the tumour was compressed. September 18th, 1877, the tumour was tapped with a small hydrocele trocar at the upper part just to one side of the middle line; six drachms of fluid were removed, and half a drachm of Morton's iodo-glycerine solution was injected, the opening being closed with collodion. For the first few days, all promised well; the tumour appeared to be firmer, smaller, and less translucent; but at the end of a fortnight it had returned to its former condition. October 5th, the operation was repeated, one drachm of the iodine solution being injected. But this was attended with the same result. On November 5th, it was injected for the third time, two ounces and a half of fluid being removed, and two drachms of the solution injected. The sac became very tense, red, hot, and tender; fluctuation persisted for a week, but on the ninth day a marked change was noted; the tumour was smaller, flaccid, elastic, but not fluctuating, and it did not become tense when the child cried. The wall of the sac became gradually firmer and thicker, and the tumour shrank. On December 14th, there being still distinct fluctuation in the now thickened cyst, it was again tapped and emptied by the removal of six drachms of a yellow viscid highly albuminous fluid; it was evident that the communication with the spinal canal was completely obliterated. One drachm of the iodine solution was injected into the sac, and well manipulated, and then allowed to escape. The tumour had since then gradually shrunk, and now presented a thick pad of skin, quite dense at the lower part, softer above, where there was a small spot which still fluctuated; from this Mr. Gould withdrew about half a drachm of yellow turbid fluid two days ago. There was no paralysis. The fontanelle was closing up. After each operation, the temperature rose to 101 deg. to 102.8 deg., and continued above the normal from two to six days; there was no convulsion or other sign of interference with the nervous system. The after-treatment consisted in thickly smearing the tumour with collodion each morning, and supporting it with wool and a bandage. The tumour evidently communicated very freely with the spinal canal, and most probably contained the spinal cord or nerves. Mr. Gould had examined twenty-three specimens of spina bifida, and had found nerves in the sac twenty times, two cases in which they were absent, and one case in which their presence was doubtful. The nerves or cord generally occupied the middle line—the position of the opaque band seen in this case. The absence of paralytic symptoms by no means favoured the opposite view. The fluid removed at the first three operations was colourless, becoming slightly turbid on standing, of specific gravity 1011, faintly alkaline, containing a trace of albumen, chlorides, and phosphates. With Fehling's copper solution, it gave no reaction; but Dr. Dupré analysed it, and after concentration was able to get distinct evidence of the presence of sugar. Because sugar could not be detected in the fluid of spina bifida, and in that escaping from the skull in cases of fracture, it must not therefore be supposed to be absent, unless the tests be applied to the fluid after evaporation. Dr. Morton's treatment had now been employed several times; and in twelve out of fifteen published cases with success. As

to the value of the glycerine, Mr. Gould stated that on pouring some of the "iodo-glycerine" on some of the cerebro-spinal fluid in a narrow glass, it was found to sink to the bottom at once and not to mix with it; and he was of opinion that the same thing occurred in injecting the tumour, for the fluid that oozed from the puncture after the injection was quite unstained with iodine, and the action of the injection had been much more potent at the lower part of the sac. Although the mode of cure resembled that seen in the radical treatment of hydrocele, there was an important difference in the two conditions, the one being a closed sac, the other communicating with a canal full of fluid. As to the fear that the inflammatory material would press injuriously on the contained nervous material, it was noted that in none of the published cases had consecutive paralysis been noted, and a specimen of Sir A. Cooper's in St. Thomas's Hospital Museum, described in his paper in vol. II of the *Medico-Chirurgical Transactions*, showed that the radical cure might take place in this way when the cord was in the sac without nervous symptoms. Mr. Gould had considerable difficulty in stopping the oozing of the cerebro-spinal fluid, which was so dangerous if allowed to continue.

The PRESIDENT said that an important subject had been brought before the Society by the full and exhaustive narration of a case by Mr. Gould. With reference to the mode of operation, he might suggest that it would be found useful to introduce the trocar and cannula through and beneath the skin some little distance to the side of the tumour. In this way, direct puncture of the sac was avoided, and the valvular puncture permitted subsequent compression (after the removal of the cannula) to prevent the escape of fluid. Whilst discussing the subject of the treatment of spina bifida, it would be of interest if members would give their experience as to the age to which patients might live, despite the deformity. For some years, a gentleman had been under his care, who had been originally attended by Sir Astley Cooper. He wore to the last a protecting case, removed from time to time, after the model suggested by Sir Astley Cooper. In this instance, there was bladder trouble, the rectum acted imperfectly, and innervation of the lower extremities was incomplete. Yet, this patient lived an active professional life, and reached the age of seventy-four years. The President added that he believed this to be the greatest age ever attained by anyone afflicted with a spina bifida.—Mr. HOWARD MARSH thought Mr. Gould's case very valuable as an illustration of the excellent results of Dr. Morton's method of treatment. He saw the patient in the Children's Hospital, and well remembered that it was suffering from a formidable variety of spina bifida such as, under former methods, commonly ended in the loss of the patient's life. He believed Morton's plan would prove a very important addition to the surgery of childhood.—Mr. THOMAS SMITH expressed his thanks to the author of the paper for bringing the subject before the Society, and his conviction that Dr. Morton had given the very best method of treatment for spina bifida that was possessed. The injections of watery solutions of iodine were very rarely successful. If sufficient irritation were excited in the sac to procure its obliteration, the inflammation was almost sure to spread to the spinal canal, as he had too often ascertained by examination. It was interesting to learn that the difference in the result of the iodo-glycerine solution was probably due to its remaining in the lowest part of the sac when injected, and, therefore, its effects were more limited.—Mr. SMITH had employed Morton's method successfully in four or more cases. He was, as yet, doubtful what effect this method of cure had on the innervation of the parts below. On this subject his colleague Mr. Baker would give some information. With regard to the President's remarks, Mr. SMITH referred to a case mentioned in Mr. Holmes's *Diseases of Children*, of a man with spina bifida aged 23, who survived an operation for stone. In his own experience, he had been consulted by a gentleman of middle age with spina bifida, who, though inconvenienced to some extent by the malady, yet was able to discharge responsible professional duties, to fulfil the functions of a husband, and who suffered from no deficient innervation of the lower parts of the body. The disease in this case had not been treated. Sufficient time had not yet elapsed to judge of the condition of patients in later life cured by Dr. Morton's method; but, as far as his own experience went, he was bound to say that, in estimating the value of the result in such cases as he had cured by other means, it would have been better for the patients had they not survived the treatment.—Mr. MORRANT BAKER said that he had employed Morton's solution for the injection of a spina bifida in an infant two months old, who was under his care at St. Bartholomew's Hospital about eighteen months ago. The solution had been prepared according to the usual formula, and was injected with the usual precautions. The local effect was good; the sac becoming thickened after the second injection, and giving no further trouble. But, at the same time, loss of power of movement and of sensibility was noticed in the lower extremities; and this had remained

to the present time. Mr. Baker thought the case should be mentioned, as it might elicit the experience of others on the subject; and would show that the injection of the iodo-glycerine solution, even when locally successful, was not without its dangers.—Mr. GOULD briefly replied.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 22ND, 1878.

CHARLES WEST, M.D., President, in the Chair.

### A CASE OF RODENT ULCER. BY C. HIGGINS, F.R.C.S.

THE patient was a married woman aged 45; her health had always been good. The rodent ulcer commenced thirteen years before admission to Guy's Hospital, at the remarkably early age of 32, as a pimple on the left side of the nose, which, however, showed but little tendency to ulcerate until five years after its first appearance. During the progress of ulceration, a second pimple, of apparently the same nature as the first, made its appearance in the angle between the right side of the nose and cheek; it did not, however, ulcerate. The eyeball, which was quite healthy, was excised, and the ulcerated surface destroyed with a paste of chloride of zinc and starch applied on strips of lint. After the separation of the sloughs, some cicatrization took place. The disease soon commenced again; and, eighteen months later, the surface of the ulcer and adjoining infiltrated tissue were destroyed with the galvanic cautery, and chloride of zinc paste was applied. The second pimple, which was enlarging, was also burnt out. After separation of the sloughs, cicatrization again took place to a great extent; but, four months later, the disease was again spreading rather rapidly. The whole of the thickened margin and base of the ulcer, together with a large amount of adjoining healthy structures, including skin, mucous membrane, muscles, and bone, were cut away with a scalpel; the bleeding was stopped with a thermo-cautery; and chloride of zinc paste was applied all over the cavity left. The wound finally healed entirely; but subsequently some recurrence of the ulceration took place, and the diseased tissues were again removed with knife, cautery, and caustic, and cicatrization again took place; and, with the exception of a small part of its outer margin, the wound has since remained firmly healed. (The patient was examined by the members present.)

Mr. GASKOIN said that he had brought to the Society a man, aged 52, who had a large oval sore, about four inches long by three wide, on the vertex. It appeared to have some of the characters of rodent ulcer. The glands were not affected. The surface of the sore was uneven, and there was a sanious discharge from it. There was no attempt at healing. The family history gave no guide to the origin of the disease. (The patient was examined by the members.)—Mr. HULKE said that he had placed on the table some specimens of rodent cancer prepared by the late Mr. C. H. Moore, who was the first to attack the cases of rodent cancer. In these and in other cases occurring in the practice of Mr. Hulke and Mr. Lawson at the Middlesex Hospital, the practice had been not to apply the caustic before cutting away as much as possible of the diseased mass with the scalpel. He had for some time given up the use of the galvanic cautery; because, if the platinum-knife were thin, it bent easily, and a thick one was not easily managed; moreover, the sense of touch became unavailable as a guide to the nature of the substance cut. Rodent cancers should be dealt with sweepingly at first, all measures being avoided which could tend to worry any remaining portions into increased activity. With regard to Mr. Gaskoin's case, he would doubt whether it was one of rodent cancer. He could not remember any case in the Middlesex Hospital in which the disease began in the hairy scalp.—Mr. GASKOIN said that he himself had some doubt whether his case was one of rodent ulcer; but Colles had described a case in which the disease commenced in the scalp. He had been struck with the remark that lupus is a disease of early life, and that rodent ulcer mostly occurred after the age of thirty. He thought, however, that lupus and rodent ulcer overlapped each other in respect to time. He had certainly seen tubercular ulcer of the face in persons beyond thirty years of age. A woman aged 65 had lately been under his care with something very like lupus in the ala and tip of the nose. He had seen the diseases in the early stage, and found that the first manifestation was not always definite; it might be felt before it was seen.—Mr. NETTLESHIP thought that it was said that rodent ulcer always began as a pimple; but probably it would be useful to have more information on this subject. He had seen a case at the Moorfields Hospital in which rodent ulcer seemed to commence in a deposit under the skin.—Mr. MORRANT BAKER said that, while it was difficult to recognise Mr. Gaskoin's case as one of rodent ulcer, it was still more difficult to give it another name. He thought he recognised

exact resemblance in the two cases in every particular, and they differed only in sex, in age, and in the duration of the disease. In the case brought forward now, the disease was in its earliest stage; in the previous one it had existed for six years, and had nearly brought the patient to the term of his existence. Both of the patients were shown.

#### HARVEIAN SOCIETY OF LONDON.

THURSDAY, JANUARY 17TH, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

*Puerperal Septicæmia.*—Dr. FITZPATRICK exhibited the uterus from a primipara, who died a few days after delivery. She had been attended by a midwife, and a small portion of the placenta and a shred of membrane were found in the uterus at the *post mortem* examination.

*Unsuspected Typhoid Fever.*—Dr. FITZPATRICK exhibited a piece of ileum with a perforation in it. It came from a woman who died after aborting. The presence of typhoid fever had not been suspected; but Dr. Fitzpatrick suspected it, and the *post mortem* examination demonstrated the surmise to be correct.

*Retroverted Uterus in the Anal Orifice.*—The PRESIDENT read a letter from a practitioner illustrating a section of his Harveian lectures. The case occurred in an old lady aged 67. The bowels were obstructed, and it was found that the retroverted uterus was plugging the anal orifice. The replacement of the womb was followed by immediate relief of the symptoms.

*The Pulse-rate considered in Relation to Post Partum Hemorrhage.*—Dr. ASHBURTON THOMPSON read a paper on this subject. The author began by referring to the well-known assertion that, if after delivery the pulse beat at or about a hundred, the patient cannot be considered safe from hemorrhage, which, on the contrary, is in that case to be apprehended. He then remarked that this assertion, which, if true, is of great value, rests upon the opinion only of a number of writers who do not offer any series of precisely recorded observations in support of it. The object of the present paper was to ascertain from a number of records of the pulse-rate in various cases, beginning immediately after delivery, what is the behaviour of the pulse in uncomplicated cases, and what its behaviour in cases of *post partum* hemorrhage. The total number of cases dealt with was sixty-three. Fifty-four of these were cases uncomplicated by hemorrhage, and nine were cases of hemorrhage of different degrees of severity, which were classified by Dr. George Johnson's method, and moreover showed the exact amount of blood lost in each. The observations, beginning within three minutes of delivery, were taken at short intervals during thirty minutes. At every observation, the watch was used, the pulse counted during not less than thirty seconds, and the result written down at the time. In cases of hemorrhage, the observations extended over a longer period. The fifty-four uncomplicated cases resolved themselves into three classes, as follow. In the majority, or thirty-nine, the pulse fell by from 3 to 29 beats (average  $13\frac{1}{2}$ ) within a few minutes—a reduction which did not always bring it below 100. In six cases, it remained absolutely steady at the rate first observed, which was not always less than 100. In nine cases, a rise from the initial rate was noticed; and if, as sometimes happened, this rise brought the rate above 100, the pulse remained at that rate for several hours. The author concluded that the pulse may fall below, rise above, or remain steady at its initial rate; that it may fall to, rise above, or remain steady at some point above a hundred; that it is very commonly irregular; and that it may intermit in cases uncomplicated by hemorrhage or by any constitutional disorder. A table showing the pulse-rate and other particulars in nine cases of hemorrhage was then shown; and the author said that for his present purpose he preferred to refer to them as cases of *post partum* inertia of the uterus, since that is the essential condition of this kind of hemorrhage, and since he wished to exclude all cases of hemorrhage from parts other than the placental site. From this table, it appeared that degrees of hemorrhage requiring active interference may co-exist with steady pulse-rates of 60 (first degree), of 70 and 76 (second degree), or with a rate varying between 96 and 108, as in one case of the third degree. It was then asked whether the causes of *post partum* inertia are always such as to influence other parts of the system as well; and observed that the condition is known to occur under a variety of circumstances in which no common element can be detected. He also observed that shock to the system is sometimes accompanied by inertia; and from five other cases (of extreme exhaustion suddenly manifested after delivery; of laceration of the uterus; sudden laceration of the perineum, and concealed accidental hemorrhage) he showed that the pulse then follows a characteristic course, increasing in frequency with great regularity as the depression progresses; and decreasing again as re-

covery sets in. Here a coincidence might be observed between the degree of inertia and the pulse-rate, which is very closely maintained, but it was coincidental, merely being the result of a systemic condition to which the inertia also is owing. This description of a characteristic behaviour of pulse in cases of hemorrhage originating in systemic depression, the author believed to be original.—Dr. CLEVELAND thought uterine inertia and *post partum* hemorrhage not so closely associated as was asserted. Some women were known as "flooders".—Dr. ARTHUR EDIS had noted that publicans' wives often flooded. Did the alcohol have something to do with it? Often *post partum* hemorrhage was due to a rent in the cervix.—Mr. CRIPPS LAWRENCE, Mr. MALCOLM MORRIS, and Dr. STEVENSON spoke; after which Dr. THOMPSON replied.

#### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 2ND, 1878.

CHARLES WEST, M.D., F.R.C.P., President, in the Chair.

*Rupture of the Uterus.*—Dr. ROPER showed a ruptured uterus. The patient was attended by a midwife. When the os uteri was fully dilated and the head nearly on the perineum, a dose of ergot was administered, and symptoms of rupture appeared an hour and a half afterwards. The child escaped into the peritoneum, and delivery was effected by version. The laceration extended through the cervix uteri and upwards as far as the right round ligament.—Dr. J. WILLIAMS had seen a case in which a similar rupture had occurred spontaneously when ergot had not been administered.

*Effect of Perchloride of Iron on the Uterus.*—Dr. HERMAN showed the uterus of a woman who had died of *post partum* hemorrhage. Her medical attendant had injected the organ with a solution of perchloride of iron—one part to four of water. This was effective for a short time only; and then a rag soaked with the saturated solution of the perchloride was pushed into the uterus. The specimen showed well the difference in the effect of the weaker and the saturated solution. The upper part of the organ, which had been bathed by the weaker solution, was, on section, unaltered to an extent appreciable by the naked eye, though it was ascertained by chemical tests that the iron had come into contact with it. The lower part of the uterus, which alone had come into contact with the saturated solution, was black, hard, and corrugated; this change extending through the inner three-fourths of its thickness.—Dr. BRAXTON HICKS said that the case showed the truth of the view generally held with regard to the effect of perchloride of iron. Healthy tissue resists the tincture, but not the strong solution.—Dr. CLEVELAND asked what was meant by the term "saturated solution". He had used the strong pharmacopœial preparation diluted with three parts of water, and thought it effective. The undiluted solution might act as an escharotic.—Dr. EDIS referred to a case of secondary *post partum* hemorrhage where a solution of iron (one to four) had been employed without permanently arresting the bleeding, in which two drachms of the strong liquor ferri perchloridi were injected into the uterus about the tenth day after delivery and allowed to remain in. The bleeding was arrested at once. The patient made an excellent though a tardy recovery. There was no sloughing or untoward symptom.—Dr. ROUTH said the case brought up the whole question of injection of perchloride of iron. He had used it twice, and both patients died. When injection into the uterus is made, there ought to be a free exit. In the case before the Society, a solution (one to four) was used; it proved inefficient, so that it is a bad plan to use a weak solution.—Dr. CORY had used it in several cases with success and without bad result; the strength of the solution being one to four.—Dr. HAYES said that the specimen showed that very little of the injection had reached the fundus, from which the blood flowed. In all cases of *post partum* hemorrhage where perchloride of iron was used, the whole of the bleeding surface should be bathed by the fluid. In order to ensure this, the uterus should be emptied of clots, and the injecting pipe carried on the hand, and the injection directed against every part of the surface. By introducing the hand into the uterus and retaining it there while injecting, a free exit was obtained for the fluid. He used equal parts of liquor ferri perchloridi and ice-water, and had most satisfactory results.—Dr. BARNES said the point of the syringe should be carried to the fundus. This could only be insured by introducing the hand into the uterus. Clots should be removed before injecting. One to four was a good strength, but a stronger solution might be used, if necessary; but it should not be escharotic. This means of arresting hemorrhage had stood the test of experience, and had saved many lives. The test for its use was the possibility of exciting reflex action. When this could not be done, perchloride of iron should be used.

*Extra-uterine Pregnancy.*—Dr. HEYWOOD SMITH showed part

illustrating extra-uterine foetation.—The specimen was referred to Drs. Madge and Aveling for report.

*Malignant Uterine Disease.*—Dr. SMITH showed a specimen of malignant disease of the body of the uterus. The patient suffered from menorrhagia and an uterine tumour. The cervix was incised, and carbolic acid was applied. She rapidly got worse, and died.

The result of the ballot for election of officers for the ensuing year was declared; and the PRESIDENT delivered his annual address.

## PATHOLOGICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 18TH, 1878.

CHARLES MURCHISON, M.D., F.R.S., President, in the Chair.

*Dermoid Cysts along Branchial Fissures.*—Mr. WAGSTAFFE gave an account of these growths in three patients. In one, they grew at the inner angle of the orbit; in the other two, at the outer angle. These last were situated beneath the orbicularis and the temporal artery, and were attached to the bone beneath. They were developed along the line of the branchial clefts. In two, they were situated at the suture of the frontal and malar bones; in the third, at the juncture of the lacrymal bone with the nasal portion of the frontal. Dermoid cysts were not always along the lines of the branchial fissures.—Mr. HULKE said such dermoid cysts, clinically, were quite distinguishable from the cystic tumours which resembled them. He had not hitherto thought of them as related to the branchial clefts. Many tumours along the embryonic clefts were not dermoid, as the common sublingual cysts for instance. Dermoid cysts were found elsewhere, too, as in the anterior mediastinum and in the ovary. In old cases, the bone underneath was dimpled by the presence of the tumour, and in one case it was even perforated.—Mr. ALBAN DORAN stated that there was one argument against and one in favour of the embryonic origin of the cutaneous cysts frequently found close to the external angular process of the frontal bone. That region lay out of the line of the clefts dividing the visceral arches, which contained the cartilaginous basis of certain bones, and such cysts lay in front of the membrane-formed frontal and malar bones. On the other hand, Professor Kowalewsky had shown that, in the embryo amphioxus, the visceral laminae completely united along the line of the mouth; then the embryonic layers at that point became fused, and the disc thus formed presented ultimately a perforation—the oral cavity. Dermoid cysts in the human face might arise in the same manner by an abnormal fusion of the epiblast with the deeper layers at one point, and the formation at that spot of a structure more complicated than the cellular tissue normally found there.—Mr. BRYANT had seen a number of such cysts, but had not thought them related to the branchial fissures. They were found in irregular positions, chiefly in the orbit. They presented no difficulties in diagnosis. He questioned if the hypothesis had anything to support it.

*Case of Paralysis Agitans.*—Dr. DOWSE said that, even at the present time, there was a difference of opinion as to the signs particularly characteristic of paralysis agitans. The patient was a woman aged 57; her age when the palsy began was 41. The agitations commenced in the head; then extended to the right arm, then to the left arm, and finally to the legs. Before her death, she was unable to stand or help herself in any way; the body was bent forward, and both the arms and legs were flexed and devoid of any voluntary power. The muscles of the calves of the legs stood out like iron bands. The intellect was clear, but the memory was failing. For three days previous to her death the tremors ceased, and she sank apparently from nervous exhaustion. At the *post mortem* examination, twenty-four hours after death, there was no cadaveric rigidity. The right lung was partially collapsed, and contained some hard nodular cheesy masses at the apex. The left lung was completely collapsed and lay flat on the inner and upper part of the pleural cavity. The heart was fatty, and the left ventricle somewhat hypertrophied. The valves were healthy. The aorta was atheromatous. The liver, kidneys, spleen, and abdominal viscera had undergone no especial gross change. The brain weighed fifty-three ounces. The convolutions and grey matter were normal. The arteries at the base were atheromatous. The nerves were remarkably firm. Upon section, the substance of the hemispheres was pale, tough, and glistening. The parts entering into the formation of the motor tract felt unusually hard. The spinal cord was equally as firm, and weighed ten drachms avoirdupois. Mr. Kesteven kindly noted the following microscopical changes. At the decussation of the anterior pyramids, the nerve-cells had undergone atrophic granular pigmentary degeneration. There was cortical sclerosis of the posterior and right lateral columns, and milky as well as colloid degeneration; and these morbid appearances were more marked in ascending in the examination of the medulla. The nerve-cells of the olivary bodies were atrophied

and undergoing fuscous degeneration. Some few of the cells in the nucleus of the ninth nerve appeared to be hypertrophied. In the nucleus of the eighth nerve the cells were deeply pigmented, and in many the processes had quite disappeared. The fibres of the auditory nerve were in some places almost displaced by milary degeneration, and also the middle of the lower portion of the nucleus of the fifth nerve. The nerve-cells of the corpus dentatum and folia of the cerebellum abounded in spots of fuscous degeneration. The corpora striata were honeycombed with milary degenerations. In the thalami optici, some milary changes were met with; but these were slight when compared with those in the striate bodies. The microscopical appearances presented by the spinal cord showed similar degenerations to those found in the brain and medulla. The cells in the anterior horns were particularly the seat of various forms of fuscous degeneration. The vessels were in some places thickened, in others sacculated, with well-marked perivascular spaces.—The PRESIDENT said that, in the case of paralysis agitans recorded by him, the typhus fever, of which the patient died, might have modified the appearances. The congestive appearances were probably due to the fever. Probably few of the Fellows had had the opportunity of examining the changes in paralysis agitans.

*Colloid Cancer of the Rectum.*—Mr. LYELL showed the rectum and adjoining parts from a woman who died in the Middlesex Hospital. She had been ill for several years when admitted. At first, there was a swelling by the side of the anus, with but little pain. Then there was a discharge, with pain; the growth increasing, but very slowly. Then the woman fell downstairs, and after that grew rapidly worse. The local distress was so great that Mr. Hulke performed colotomy, which gave great relief. The woman died eighteen months afterwards. The disease during that time had spread over the buttocks. At the *post mortem* examination, the other organs were found healthy. The channel of the rectum was quite destroyed, and the coats were glued together for two inches. The disease extended three inches further up the posterior and outer wall. It quite filled the ischio-rectal fossæ. The extension over the buttocks was more marked over the left than the right side. There was a large ulceration. The skin in some parts peeled off easily. Much of the mass was soft and gelatinous; other and later portions were firmer. It was a rare form of rectal cancer, and was interesting clinically from its long duration. Colloid cancer ran a longer course than other cancers. This woman had had the disease for more than five years. No other parts were implicated, except two large glands in the inguinal region.—Mr. BRYANT had had a like case in a female aged 50, who had rectal stricture for two or three years. The obstruction was so great that colotomy was performed. A large mass, of the size of the closed fist, existed at the left side of the pelvis. The woman lived eighteen months afterwards, without any pain. The mass in the pelvis grew into a large projecting fungating mass, which ulcerated. A little fecal matter appeared through the ulceration. She sank ultimately from exhaustion.—Dr. MAHOMED said that, as to the duration of colloid cancer, he knew of a case where malignant disease of the œsophagus existed for nineteen years. At last, colloid cancer of the spermatic cord set in and spread, leading to a fatal issue.—Mr. HULKE said that colloid cancer was slower in progress than other forms affecting the rectum. He knew of a man who had such cancer, and yet worked for two or three years. Four or five years previously, he had been cut for fistula. The disease quite filled the ischio-rectal fossæ. The unequal manner in which the skin was implicated might be useful in diagnosis.

*Diaphragmatic Hernia.*—Dr. GARLICK related a case of this lesion in a child, whose mother was consumptive during her pregnancy. The child was always weakly. When six months old, it had a severe cold; and at eighteen months, severe vomiting, with obstinate constipation. It had pains in its belly. At two years, it ran about without obvious dyspnoea. It was two-and-a-half years old when severe vomiting came on. It was very thirsty. Screaming preceded the vomiting. At last it became collapsed, with a retracted abdomen. On *post mortem* examination, it was found to be pigeon-breasted, mostly on the right side. In the right pleural cavity, there was what appeared to be a tumour. It consisted of diaphragm, peritoneum, and the pyloric end of the stomach. The liver was tilted forward. The right lung was hollowed by the tumour so that there was no heart displacement. If not congenital, it was evidently of long standing. The viscera were drawn in by inspiration.

*Phosphatic Diabetes.*—Dr. RALFE exhibited some urine from a patient admitted into the Seamen's Hospital last November. The patient was much emaciated, and was suffering from slight bronchitis; this, however, passed off in a few days, and no other definite symptoms were present to account for the emaciation and continued debility. The urine was carefully examined, and found to contain no albumen or sugar.

The urine was then collected for twenty-four hours, and was found greatly increased in quantity.<sup>1</sup> The urea and phosphoric acid were determined by Dr. Murphy with the following results :

	Quantity.	Sp. grav.	Urea.	Phos. acid.
December 3rd	4470 grm.	1.011	67.1 grm.	5.3 grm.
December 4th	4900 "	1.016	116.4 "	9.1 "
December 5th	1400 "	1.018	103.0 "	7.0 "
December 7th	3100 "	1.017	61.2 "	4.2 "

The observations were confirmed by Dr. Ralfe in a subsequent analysis, made December 13th, with standard solutions distinct from those used by Dr. Murphy. The patient remained more than a month in hospital, and regained somewhat in weight and strength. During his stay in hospital, the patient suffered considerably from boils. Dr. Ralfe said the case corresponded with those originally described by Prout and subsequently by Roberts : of diuresis, accompanied by an increased elimination of urea. These observers, however, had not noted the increase of phosphoric acid, which had first been done by Dr. Dickinson in 1875 ; subsequently, Dr. Tessier of Lyons, in a pamphlet entitled *Du Diabète Phosphatique*. Dr. Tessier, however, contended that these cases were distinct from the azoturia of Prout. Dr. Tessier divided these cases into three clinical groups : those (1) in which nervous symptoms are prominent ; (2) those which precede or accompany pulmonary affections ; (3) those which alternate with or are followed by true saccharine diabetes. Whether a closer connection between the "azoturia" of Prout and the "phosphaturia" of Tessier can be established, further observations must determine. The present case showed that both might exist together.—In answer to a question from the PRESIDENT, DR. RALFE said he was not acquainted with the termination of any case of polyuria.—MR. NUNN remarked upon the large amount of urea present in these cases.

**Aneurism of Cerebral Arteries.**—Dr. GREENFIELD exhibited five aneurisms. One was an aneurism of the basilar artery at its bifurcation. The patient died with symptoms of cardiac disease. The brain was healthy on the upper surface, but there was a large quantity of fluid present. A firm coagulum enclosed the circle of Willis. The nerves were not implicated. The arteries at the base of the brain entered the mass. There was a bulging in the left ventricle, which was the sac of the aneurism. In the circle of Willis was a circular sac. The vessels were not adherent to it. The sac was thick-walled, and in its centre was some blood, nearly coagulated. The sac did not compress any important part. The aortic and mitral valves were both diseased, having prominent vegetations : some filiform, some club shaped. There were no fibrinous deposits. The second aneurism occurred on a branch of the internal carotid, in the cavernous sinus. It was found in a female aged 22. It was of the size of a pea and was completely curved. The patient had hemiplegia and heart-symptoms. There was calcified vegetations on the mitral valve. Numerous infarcts were found. The third case was that of an aneurism in the brachial artery, at its bifurcation. There was double aortic disease. Pain, with swelling, appeared suddenly at the bend of the elbow. The brachial artery was ligatured ; but the man died of pneumonia. The operation was successful, and a firm clot was found covering the arteries. The ulnar nerve was stretched. The walls of the artery were thinned, and an extensive rupture of a crescentic form was found. There were traces of a sac. The aortic valves were diseased, and a long vegetation from them had caused an aneurism in the mitral flap, at the point of contact with this vegetation. The fourth specimen was a miliary aneurism, which ruptured in a man aged 40, who was brought to the hospital in a comatose condition, and of whom there was no history. On *post mortem* examination, there was found an effusion under the arachnoid and also at the base. The convolutions of the left hemisphere were flattened, and there was some hemorrhage in the cerebellum. A mass of blood was found in the left ventricle ; it extended into the left corpus striatum. It arose from a branch of the left middle cerebral artery, and there was a hard mass at that point. The effused blood had ploughed a track like a bullet track in the line of least resistance. The fifth case was that of a miliary aneurism in the left corpus striatum. It occurred in a man with cirrhotic kidneys. There was an old clot in the right corpus striatum.

LEEDS.—The births were at the annual rate of 41.1 and the deaths 22.9 per 1,000 in October, and from zymotic infectious diseases 3.2 per 1,000, which is above the average. Dr. Goldie reports an outbreak of scarlatina at Hough End, in consequence of an infected family moving into the village, and afterwards through children attending the schools whilst still peeling. The drainage of some houses is described as very bad, giving rise to a case of typhoid ; and what makes the matter worse is, that they have been recently constructed, and are not fit for human habitation.

SATURDAY, FEBRUARY 2ND, 1878.

### THE LOST MEDICAL SCHOOL.

THE present discussion of the causes which have led to the despoilment, degradation, and ultimate banishment of the Faculty of Medicine of the University of Oxford, the diversion of its endowments, and the destruction of its school, has hitherto been conducted without the benefit which would undoubtedly have been derived from the direct intervention of Dr. Acland, and the statement of his views. The case, as it has been stated thus far, is a very remarkable one. Our correspondents have pointed out that the abolition of medical teaching has proceeded by slow steps, which have recently been somewhat hastened and appear to have now reached their climax. The three offices of Regius Professor of Medicine, Aldrichian Professor of Medicine, and Lord Lichfield's Medical Professor, have been combined for the first time in the person of one accomplished physician, Dr. Acland himself, with definite duties of lecturing in accordance with the endowments, but with the net result, according to the statements which have been made to us and which have not yet been contradicted, that these duties have never yet been performed, and that the three offices thus combined have practically contributed nothing to the medical teaching which they were intended to afford. At the same time, the Linacre and Lee endowments, for the teaching of human anatomy and physiology, have equally been diverted from the science of medicine, to which they were specially dedicated by their founders ; and by these means the Oxford School of Medicine has been effectually stifled, and the name of the Faculty erased from the official publications. We have found it difficult, in the first instance, to accept as credible the remarkable history of which the outline has been sketched in the letters of our correspondents to which we have on previous occasions adverted. Still more difficult is it, it would appear, to understand the reasonableness of any theory by which such a course of action could be explained. The only defence yet attempted here has been the singularly fragile suggestion of Dr. Chambers, that the Radcliffe Infirmary, with its two hundred beds, not to speak of other medical resources of a city of thirty thousand inhabitants in the centre of a populous county, was incapable of affording that clinical material such as could nourish a practical medical school. Against that hypothesis we quoted at once the University of Göttingen, in a population of seventeen thousand ; the University of Heidelberg, in a population of twenty-two thousand ; the University of Bonn, in a population of twenty-eight thousand ; and the University of Würzburg, one of the most famous in the world for its medical school, in a town which has a population of only forty-five thousand. We might have also referred to Trinity College, Dublin, which has reached so high a standard of reputation in its medical school, and in which the medical school has added no little to the greatness and reputation of Trinity College, although its clinic hospital could never yet boast more than a hundred beds. Stokes and Graves both taught in a hospital of a hundred beds, and made the teaching of their school celebrated throughout the world. The more, indeed, the argument is investigated, the more shallow and perfunctory it will be seen to be ; and it is hardly conceivable that it should be seriously put forward as a basis of justification for the perversion of the endowments of medicine in Oxford, and for the destruction of the birthright of this generation of medical students and of their share in the great teaching powers and great influence for culture of the premier University of Great Britain.

We publish, however, to-day, in another column, a document, of

which we have only lately received a copy, but which is included in the papers issued at the University in March 1877. We have there a summarised statement by the Regius Professor, Dr. Acland, of what, in his opinion, is "most needed" at the present time in the department of medicine in Oxford. There is another fuller paper of a preliminary kind to which we may subsequently revert. Meantime, this is the latest statement of which we have cognisance expressing Dr. Acland's views, and we have ground for treating it as setting forth what he really considers to be the immediate necessities of that which is described as the "Department of Medicine". The faculty having been abolished and the school cru-hed, there remains apparently a nominal department of medicine. After reading that document, we believe that most medical men will look with something like bewildered astonishment, bordering on despair, at the prospect that lies before them. Here we have a Regius Professor of Medicine and a Clinical Professor of Medicine, who, during the whole term of his office, extending over nearly twenty years, has never, as far as we can find, given either a course of lectures on medicine or a course of clinical instruction in medicine; whose notices to students that he would meet and confer with them, with the view of making arrangements for such course, have never resulted in anything but vacuous emptiness; and whose office of triple professor exists apparently only in derision of what the teaching of medicine is generally understood to mean. The first paragraph of his statement as to what is most needed runs: "I should retain the office of Regius Professor of Medicine as at present." Of course, Dr. Acland means this to have no personal application, nor do we. He only means that he should advise the office of Regius Professor being retained; but when he advises that it should be retained as at present—that is to say, as a combination of offices, to neither of which do any active duties apparently belong, nor are any fulfilled, he strikes at the whole root of the matter, and there we are compelled to differ from him, and so will, we believe, the whole profession of medicine differ from him *toto calo*. The subsequent paragraphs throw a not less curious light on the fantastic and aberrant scheme which Dr. Acland gravely sets before the commission as constituting the most pressing needs of the department of medicine in the University of Oxford. Here is a department of medicine, so called, in which the Medical Professor gives no medical lectures, in which the Clinical Professor gives no clinical lectures, in which the Professor of Physiology teaches no human physiology, in which the Reader in Anatomy teaches zoology and biology, and in which there is no professor of surgery, of histology, or of human pathology; and the most pressing needs of that department Dr. Acland considers to be that the Regius Professor shall have the assistance of a person whom he describes as an analyst and demonstrator of medical and sanitary chemistry and micro-copy; second, that a professor should be added for comparative pathology, and that funds should be provided for an occasional lecturer on such subjects as the combined results of mathematics, physics, physiology, pathology, and therapeutics, in the investigation of the organ and function of vision. Now, of course we all know that Dr. Acland has given attention to the subject of national health, and he gave lately a popular lecture on rabies, which has since been printed in a lay review; and that some years since he delivered an interesting lecture on the subject of vision at the College of Physicians in the presence of Royalty; but it passes imagination that, in such a state as the medical department of Oxford has fallen into, he should seriously propose that permanent teaching in these three fancy subjects of his leisure moments should be considered as among the most pressing needs of the department of medicine in the University of Oxford. We speak with great respect both of Dr. Acland's acquirements and of his objects in making these propositions, but we cannot help regarding them as aberrations of a man whom the consideration of the external collateral relations of medicine has diverted altogether from the main points at issue.

When the department of medicine at Oxford becomes really worthy of the name of a department of medicine, in the sense in which it is understood in any university in the world, or in any medical school in the world, there may be time to think of and reason to carry out such suggestions; but with the medical department, so called, which is deprived of all the essential character and endowments of a medical department, which teaches neither medicine, clinical medicine, anatomy, histology, pathology, nor any of the fundamental scientific groundworks of medicine, to talk of international hygiene, and the pathology of animals, as the most pressing needs of the University of Oxford, is to depart from every known standard of reasonable requirements, and take the most effective means which could be devised for perpetuating the existing abuses. This is the mere fringe of medicine; and the proposition is as wise as it would be to suggest supplying costly and elaborate decorations of a garment which does not exist, or for which no means of fashioning are provided. Dr. Acland might as well present a shirt-frill and a set of gold studs to a naked lay figure as institute these outside professorships in a department of which the very backbone of scientific medicine is wanting, and which has not yet been clothed with a rag of the requisite drapery for its stately figure.

In the earlier document, however, Dr. Acland sets out "three strong arguments" which apparently form the basis of these suggestions. They are, "1. That a purely scientific school of biology, in the widest sense of the word, is a national want; Oxford has entered on providing it, and has yet very much to do towards the completion of it; 2. That the opportunities for the practical study of medicine in our great metropolitan hospitals are unsurpassed in the world, and that similar opportunities cannot be found in Oxford; and 3. That the University cannot afford to incur the danger to its science school of having to adapt itself to imperfectly trained pass students in medicine, whose interest it would be to drag down the teaching of its science classes to the minimum of professional requirement. For this reason alone, the University should free itself of all responsibility with regard to 'applied' departments, which it cannot entirely regulate." Fairly analysed, what does all this mean? Is it a fact, that having to train pass students drags down the requirements of an university school? Let all great universities which do undertake the training and examination of medical students answer. Has it dragged down the Faculties of Edinburgh, of Dublin, or any of the great foreign universities which we have named? or has it dragged down the requirements of the University of London? Is it not rather the fact, that the existence of the Oxford School, with high acquirements and with magnificent collateral endowments and opportunities for study in all directions, would elevate the whole tone of medical teaching, would bring to Oxford a considerable contingent of students who would prepare themselves to follow the highest paths of medical science, and from whom would be recruited a race of calm scientific thinking men, students, demonstrators, teachers, and professors, to whom we should look to maintain the highest standards of philosophic thought and studious exercise of their art? Has the necessity of training a vast proportion of mediocre pass students in abstract subjects for the Arts Degree at Oxford dragged down the character of the honours classes in other subjects, such as classics and mathematics? What a poor trembling suggestion is this, of annihilating the faculty and evading the whole duty of medical training for fear that Oxford, of all bodies, should be unable to resist the temptation of lowering its standard. How strange an excuse to allege for having already lowered the standard for teaching in anatomy, in physiology, and in medicine, to a point below the requirements of any examining bodies, so that no student can now obtain at Oxford the certificates which will avail at any examining body for any department of medicine, or for the preliminary scientific medical studies.

Then, as to the "strong argument", that the opportunities for the

practical study of medicine in our great Metropolitan Hospitals are unsurpassed in the world, and that similar opportunities cannot be found in Oxford; what does this mean if analysed? Let it be granted that, at some great hospitals and schools, the clinical staff and the clinical facilities will always be of a higher class, in some particulars, than would be probable or possible at Oxford; but, not only are London schools most unequal in this respect, not only is it apparent to every one that no London school approaches in completeness of its teaching power the *ensemble* which might be collected at Oxford; but, of course, in respect to many minor London schools, any comparison would be absurd. London schools have their strength; but from their very multiplicity, and from the fact that the offices are largely filled by busy practitioners who look not to science, but to fees, for their career, a large proportion of lectureships are always in every school notoriously imperfectly filled by teachers who accept them temporarily, not because they are the special subjects of their predilection or of their knowledge; not because they afford the staff on which they might rest in their scientific career; but as mere temporary stepping-stones on which they tread, passing hurriedly, as occasion serves, from one to another, until they reach successful practice. As to clinical practice, Oxford, with its two hundred beds, could probably never expect or desire to have more than one student for every two beds; while, at many of the London hospitals, there are three or four students to each bed. Every one, of course, recognises the fact that, however perfect the Oxford Medical School were made, however perfect, we hope we may add, it may yet be made, there will be left in the career of the student ample time to supplement his clinical experience by a year's residence in any of the great clinical centres.

Meantime, the Department of Medicine at Oxford has been bitterly described by its own sons, in the letters which we have published, as a shame and a derision; and we cannot think that, if the proposition, which we have printed elsewhere, of Dr. Acland, as representing the fulfilment of its most pressing needs, were carried out, it would then be nothing more or anything better than it now is. Such additions would only depart still more widely from the recognition of the real needs of the Medical Faculty at Oxford; they would do nothing to provide the basis of the first scientific teaching of medicine, which, at least, is the most pressing duty of Oxford to supply in a complete form; they would do nothing to attract medical students, or to satisfy them when attracted. We again repeat that, even in the interests of the purely scientific department of biology, the presence of a class of medical students affords at once the only probability of sufficiently stimulating the energies, or justifying the existence, of a complete staff of teachers of biology. Without a class of medical students, the biological department and the medical department of Oxford will only remain the fanciful toys of academic taste. With it, they would acquire solidity, firmness, and vital force. Medicine, and medicine alone, crowns the edifice of biology. The systematic divorce of biological study can only lead to nullity, and in the perpetuation of the simulacrum of teaching which is now known as the Medical Faculty of Oxford.

#### M. RANVIER'S LECTURES AT THE COLLEGE OF FRANCE.

THE lectures delivered last year by M. Ranvier, Professor of Histology at the Collège de France, Paris, have just been collected and published by Dr. Weber, his assistant and collaborator. The subject of the course is the histology of the nerves. The mode of termination of the ultimate nerve-tubes in the striped muscular tissue, and in the electric apparatus of the torpedo, has been more particularly the object of M. Ranvier's researches; but he also treats, in an exhaustive and original manner, of the intimate structure of the medullated nerve-tubes, of the connective tissue and vessels of the nerves, of Re-

mak's fibres, and of the degenerative and regenerative changes that occur on the section of nerves. These lectures are critical as well as practical; and M. Ranvier not only gives the results of his long and patient labours, and indicates in a precise and practical manner the methods by which the same studies may be pursued, but also passes in review, with judicial and scientific acumen, the researches of his predecessors in the same field of inquiry. It is this lucid explanation of what he himself sees and thinks, combined with a profound knowledge of the views and researches of others, that make M. Ranvier's lectures peculiarly interesting both to hear and read.

This year, the professor is treating, in his course, of the nervous system of the heart, and will proceed to that of the unstriped muscular tissue and of the glands; and also, if time permit, he will explain the termination of the nerves of the skin. *A propos* of this last, M. Ranvier has lately made an important communication to the Académie des Sciences. In studying the tactile corpuscles, he has found that, in the beak of the duck, the nerves which enter these corpuscles do not terminate in a single cell, as many observers have affirmed, but by a sort of disc of a nummular form, rounded at the edges, situated between two cells which are cartilaginous in appearance. In the most simple form, there is one disc between two cells; but there are also groups of three cells and two discs, four cells and three discs, and so on. "Sometimes the nerve-tube which is distributed to a tactile corpuscle sends out at each cellular space a branch which is attached to a special disc; at others, it passes into an intercellular space, becomes enlarged so as to form a tactile disc, and reconstitutes itself on the opposite side to form the next disc. The disposition is not without importance to the physiology of the sensitive nerves: a nerve-tube which has already furnished a lateral ramification to a tactile corpuscle will divide and give a secondary branch to terminate in a neighbouring corpuscle." The tactile disc, stained by osmic acid and double chloride of gold and platinum, and viewed under every variety of section, seems to M. Ranvier to be an expansion of the fibres of the cylinder-axis. "From this description", says M. Ranvier, "it results that the tactile disc, truly a nervous and sensitive organ, is protected from mechanical irritation from without by the special cells which surround it. On this account, it cannot receive an impression except in an indirect manner. I think even that the contact of external objects acts at first upon the cells of the corpuscle, and, by a mechanism unknown to us—perhaps by the production of electricity, heat, or a chemical substance irritating to the nerves—reacts in its turn on the tactile disc. This is an hypothesis of which the only value is, I acknowledge, that it may lead to new researches."

In conclusion, M. Ranvier remarks that the tactile corpuscles in the human finger, although much more complicated, are similar to those in the beak of the duck; and that he hopes soon to communicate to the Academy of Sciences the results of his investigations on this subject.

These interesting and minute researches are not without their practical and medical value; for it is probable that, when the normal anatomy of the tactile corpuscles is known, and the methods for studying them shall have become the common practice of histologists, many of those curious forms of perverted or abolished cutaneous sensation may receive a rational explanation, and their treatment, instead of being purely empirical as at present, may be based on an intimate knowledge of the morbid processes undergone.

DR. THOMAS J. ROWELL of Singapore has been appointed Principal Civil Medical Officer in the Straits Settlements by Lord Carnarvon. The office is one of the most valuable in the gift of the Minister for the Colonies.

MR. ERICHSEN, F.R.S., Surgeon-Extraordinary to the Queen, has consented to preside at the annual festival in aid of the funds of the University College Hospital, to be held at Willis's Rooms, on Tuesday, the 21st of May next.

OUR correspondent in Rome writes :—Scientific men in Great Britain will learn with deep regret that Padre Secchi is affected with cancer of the stomach.

DR. E. SYMES THOMPSON has been elected Physician to the Equity and Law Life Assurance Society, in the room of the late Dr. R. Payne Cotton. There were thirty-eight candidates for the appointment.

To the three Universities of Leyden, Utrecht, and Groningen in Holland, a fourth has lately been added by the formation of the Athenæum at Amsterdam into an University. Among the professorships in the Faculty of Medicine is one of History of Medicine, to which Dr. Abraham H. Israëls has been appointed.

#### CLAPTON ASYLUM FOR IMBECILE CHILDREN.

ON Thursday, January 24th, the annual new year's entertainment was given to the patients in this Asylum. It consisted of a concert, in which the children alone took part; a novel feature being a musical performance by the inmates' life and drum band. Then followed a burlesque, acted by the staff and inmates under the direction of Dr. Fletcher Beach, the medical superintendent. This seemed to afford great amusement to the children. The proceedings closed with the playing of the National Anthem by a very skilful stringed band.

#### ROYAL FREE HOSPITAL.

THE new Victoria wing of the Royal Free Hospital, Gray's Inn Road, which provides accommodation for fifty additional beds, was opened on January 24th, in the simplest manner, by the Committee of Management of the Hospital. Mr. James Hoggood, the chairman, declared the new wing to be formally opened; a prayer was offered by the chaplain of the Hospital, the Rev. Robert Maguire, D.D., and the simple ceremony finished. When the other new works for the enlargement of the Hospital, which will be proceeded with immediately, are completed, a more ceremonious opening of the whole will, it is understood, take place; and for that reason the proceedings on Thursday week were conducted in the quiet form described. The Victoria wing consists of three new wards and a spacious out-patient department. Each ward is one hundred and five feet long and twenty-two feet wide, and contains sixteen beds, thus affording two thousand cubic feet of air to each patient. Two handsome drinking fountains have been presented by two ladies for the out-patients' waiting-rooms. The new wing has been erected from designs and under the superintendence of Mr. William Harvey, architect, Whitehall, at a cost of about £13,000, which has been defrayed out of legacies recently bequeathed to the hospital. The estimated cost of the proposed new additional buildings, which will provide accommodation for the nurses, and also isolated wards for the reception of contagious and infectious cases, is £8,000; and contributions towards this object will be thankfully received by the treasurer, Mr. Edward Masterman, 27, Clement's Lane, E.C.; by any of the London bankers; and by the secretary at the hospital.

#### DEATH UNDER CHLOROFORM.

WE have made inquiries as to the death from chloroform, reported last week to have occurred at the Devon and Exeter Hospital. From a communication kindly made to us by Mr. H. Gordon Cumming, House-Surgeon to the Hospital, we gather the following outline of the facts. The patient, a well-developed and healthy-looking lad, aged about eighteen, was about to undergo the ordinary operation for the removal of an elongated and indurated prepuce following soft sores. The administration proceeded satisfactorily for two or three minutes, and the boy was becoming anaesthetised. A severe spasmodic stage then supervened; a change being noticed in the patient's appearance, the chloroform was at once withheld. This change consisted in a sudden lividity of the countenance and sudden dilatation of the pupils. Every effort was at once directed to restoring the patient: cold water was dashed on the face and chest, air freely admitted into the room, and artificial respiration kept up for a long period. Only about one drachm

of chloroform was found to have left the drop-bottle, and the portion sprinkled on the mask, just before its removal, still remained, so that the lad could not have been exposed to the vapour of one drachm. The heart had been previously examined, and nothing found to contraindicate the anaesthetic. No *post mortem* examination could be obtained, in spite of much persuasion with the friends.

#### DEATH FROM SELF-ADMINISTRATION OF CHLORAL.

ON Saturday last, Dr. Diplock held an inquiry at Sutton, near Hounslow, touching the death of Mr. Thomas Edward Lucas, aged 48, of Sutton. Mr. W. J. Lucas, a brother, stated that deceased was of no occupation, but formerly practised as a solicitor. Deceased had for some time been suffering from illness, and was depressed in spirits. He also complained of want of sleep. He had never made an attempt on his life. On Thursday, deceased did not come down from his bedroom, and witness, going up, found the door locked. He obtained a ladder, and got in at the window, when he saw the deceased lying dead in his bed. Dr. Henry Bullock, of Spring Grove, said he was called to the deceased, whom he found dead. There were two bottles in the room, and they had recently contained chloral. Deceased had been in the habit of taking it, and witness was now of opinion that he had taken an overdose. Deceased's death was caused by the quantity of chloral taken. After some deliberation, the jury returned a verdict of "Death from an overdose of chloral".

#### THE DISTRESS IN SOUTH WALES.

THE reports of Mr. E. W. S. Davis, Medical Officer of Health of the Aberdare district, for the quarter ending December 31st, is of interest as showing the state of health in the district in which there is at present a great deal of want and distress, although not, we understand, to the extent which was reported. At this time of the year, there is commonly much want and suffering amongst the poor in this district, which is now much aggravated from the terribly depressed state of trade. It is satisfactory to see that the district is perfectly free from fever, and to note the absence of any deaths from typhoid fever since the Board of Health has been established there. The mean death-rate of the year is 19.4; less than half the birth-rate, which stands at 39.2. Mr. Davis mentions the marked frequency of the occurrence of semi-epileptic attacks among the poor wanting food. Many such cases have occurred among Lady Aberdare's poor clients. These attacks, which seem to have some relation to the effect of the nervous symptoms of want of food, have, it is suggested, a certain clinical interest in relation to the somewhat similar symptoms noticed in the Penge case.

#### THE MEDICAL REGISTER.

IN the Queen's Bench Division of the High Court of Justice, on January 28th, before the Lord Chief Justice and Mr. Justice Manisty, an application was made by a medical man, who had been struck off the *Medical Register*, for an order on the Medical Council to restore him, the ground of his application being that his name had been removed on some charge of misconduct without a hearing. Mr. Pope, Q.C., and Mr. Pollard, were for the appellant; Mr. J. Brown, Q.C., and Mr. C. Bowen, were for the Council. The Lord Chief Justice, in the course of the discussion, in which it was urged by the counsel for the Council that they had a discretion as to removing or restoring names of medical men on the *Register*, observed that he did not think there was a power to remove the name of a medical man on representations of professional misconduct without a hearing. If a medical man were to have his name struck off the *Medical Register* for professional misconduct, he ought to know what the charge was, and have an opportunity of making a defence. The Council, therefore, ought, in the opinion of the Court—assuming the proper qualification and on proper inquiry—to entertain the application for restoring the applicant's name. Upon this intimation of opinion, the counsel for the Council declared that they would act in accordance with it. The counsel for the applicant pressed that a *mandamus* should be issued to the Council, and that there should be no condition as to inquiry; but as to this, the Court

observed that it might be a question whether a *mandamus* could lie issued to the Council to put any person's name on the *Register*, as they were to insert the names of those they thought fit and had a duty to discharge.

#### LEGISLATION ON THE OFFICE OF CORONER.

IT is with great satisfaction we perceive that the Government has already taken this important subject in hand. The first instalment of reform refers to the antiquated mode of electing coroners by the votes of freeholders. This is to be entirely abolished, and a new method of appointment substituted. Mr. Sclater-Booth introduced a Bill into the House of Commons on Monday last, for constituting County Financial Boards. These Boards will consist of a certain number of members for each county, representing both owners and occupiers, and they will be empowered to survey and direct the general interests of the county. Among other changes, it was proposed that the "time-honoured institution" by which coroners were now elected should be abolished, and that, in future, the selection and appointment of these officers should be committed to the new County Boards. This was described by Mr. Sclater-Booth as one of the most radical of all the provisions of the Bill, but he believed it was one which would meet with but little opposition on either side of the House. This change will necessarily lead to another, namely, that certain qualifications will in future be required of those who offer themselves for the coronership. House-agents and retired tradesmen will be excluded under this system, and there will be an end to that bribery and corruption which have hitherto marked some contested elections for coronerships.

#### THE PUBLIC HEALTH.

DURING last week, 5,669 births and 4,017 deaths were registered in London and twenty-two other large towns of the United Kingdom. The natural increase of population was 1,652. The mortality from all causes was at the average rate of 25 deaths annually in every 1,000 persons living. The annual death-rate was 24 per 1,000 in Edinburgh, 27 in Glasgow, and 29 in Dublin. The annual rates of mortality per 1,000 last week, in the twenty English towns, ranged in order from the lowest, were as follow: Portsmouth, 15; Hull, 16; Leicester, 17; Nottingham, 17; Oldham, 17; Bradford, 19; Bristol, 19; Salford, 21; Leeds, 21; Norwich, 21; Sunderland, 21; Sheffield, 23; Wolverhampton, 24; Birmingham, 24; Newcastle, 24; Manchester, 26; and the highest rate, 27, in Brighton, Plymouth, Liverpool, and London. The deaths from small-pox in London declined to 34, and no death was referred to this disease in any of the nineteen provincial towns. In London, 2,430 births and 1,864 deaths were registered. The annual death-rate from all causes, which in the two previous weeks had been equal to 25.7 and 27.8, was last week 27.2. The 1,864 deaths included 34 from small-pox, 63 from measles, 39 from scarlet fever, 6 from diphtheria, 117 from whooping-cough, 32 from different forms of fever, and 13 from diarrhoea; thus to the seven principal diseases of the zymotic class 304 deaths were referred, against 299 and 291 in the two preceding weeks. Whooping-cough caused 117 deaths last week, against 69 and 94 in the two preceding weeks. The fatal cases of measles, on the other hand, further declined to 63, from numbers which had decreased from 109 to 77 in the four preceding weeks. The deaths referred to fever, which had been 33 and 21 in the two preceding weeks, rose again last week to 32, and were but 2 below the corrected average; 3 were fatal cases of typhus, 23 of enteric or typhoid, and 6 of simple continued fever. The deaths from small-pox, which had been 26, 35, and 51 in the three preceding weeks, declined to 34 last week. Of the 34 fatal small-pox cases, 13 were certified as unvaccinated and 11 as vaccinated, while in the remaining 10 cases the medical certificates gave no information as to vaccination. The number of small-pox patients in the Metropolitan Asylum Hospitals, which at the beginning of October last had declined to 137, has since steadily increased to 415, 468, and 505, at the end of the last three weeks; 126 new cases were admitted during last week, against 124

and 129 in the two preceding weeks. The Highgate Small-pox Hospital contained 55 patients on Saturday last; in the four preceding weeks, the numbers had steadily increased from 26 to 47. In Greater London, 2,958 births and 2,139 deaths were registered, equal to annual rates of 34.7 and 25.1 per 1,000 of the population. At the Royal Observatory, Greenwich, the duration of registered sunshine in the week was 11.6 hours, the sun being above the horizon during 60.4 hours. The recorded duration of sunshine was, therefore, equal to 19.2 per cent. of its possible duration.

#### PRISON DISCIPLINE AND DISEASES OF CONVICTS.

THE inquest which took place on the 16th instant on the body of Ex-Colour-Sergeant M'Carthy, one of the released Fenian prisoners, who died at Morrison's Hotel on the previous day, involves several points of considerable importance, especially in its bearing upon gaol discipline and upon the diseases of convicts. The report, in the *Daily Express*, shows abundant evidence of local political excitement, and of a certain degree of personal sympathy in the circumstances of the deceased, which is hardly likely to influence general public opinion. We have nothing whatever to do with this matter in its political aspects. Every impartial reader of the evidence must, we consider, agree with us in thinking that the evidence, as reported, was almost absolutely *ex parte*, consisting, as it did, of the medical testimony to the effect that M'Carthy, a man aged 44, who had been imprisoned in various gaols for twelve years, died of cardiac and pulmonary disease (dilatation of a fat or fatty heart, some tuberculosis, and considerable pleuritic effusion); and of the statements of certain of his fellow-prisoners—released Fenians—who declare that he was ill-treated, ill-fed, and overworked. On the part of the prison authorities, whose system this verdict seriously impeaches, we have not a syllable of evidence. We understand that the case has become the subject of official inquiry and report; and, until the publication of such report, we must refrain from concurring in the very decided opinion attributed in the newspaper report to one of the medical witnesses, "that the disease of the heart in this case was so marked and so intensified that perfectly satisfactory evidence must have been present to satisfactorily demonstrate to any medical man carefully examining the heart of the deceased two years ago, that he was utterly unfit to undergo prison discipline; and from 1876, as sworn to, if true, that he had to approach the ventilator for want of air—want of breath, as he would feel—from that moment commenced a slow death but sure [*suppressed applause*]. He would say, also, that the condition of the lung and the extreme fatty degeneration of the heart must have been apparent to the medical eye and to the unprofessional eye such as to excite the greatest sympathy." Newspaper reports of medical evidence are so proverbially inaccurate, that we cite the above only as representing the present aspect of the question at issue. We consider that, quite apart from the merits of the present case, a full inquiry by the Inspector-General of Gaols will be useful in its bearing upon a point which has considerably exercised the thoughts of many interested, as physicians and philanthropists, in gaol management, viz., the proper mode of dealing with persons advanced in life or not habituated to manual work, who are sentenced to hard labour in gaols or subjected to like discipline in workhouses. Of course, the law humanely permits the gaol and union authorities, and especially the medical men, considerable judgment and latitude in all such cases; still we doubt, upon considerable personal knowledge and direct experience, whether the operation of this humane system of check is absolutely sure, even, and adequate. We know three countries in which, not many ages ago, criminals were systematically flogged to death; we should be glad to feel satisfied, as we are not at present, that our law had rendered it impossible that any criminal or pauper in the United Kingdom and its Colonies should, however undesignedly, be subjected to the still more terrible penalty of being gradually worked to death. We know it to be a fact, that when, thirty years ago, the prisoners in a London house of correction were worked on

the treadwheel and inadequately fed, cases of dilatation, or more strictly speaking of stretching of the chambers of the heart, became very frequent among them. We shall watch the progress of the M'Carthy case with considerable interest, but from an exclusively medical point of view.

#### THE HEALTH OF PIUS IX.

FOR a week or ten days before the death of King Victor Emmanuel, the Pope had been able to leave his bed-room, and to hold receptions in the private library adjoining. He seemed to gather strength, and rapidly to regain his vivacity. There is no doubt, however, that he is most susceptible to atmospheric changes, as there were again alarming rumours about his state towards the middle and end of last week. He really, however, seems only to have suffered from a slight exacerbation of the rheumatic pains, which keep him wakeful and retard his recovery from the serious illness in the end of last year.

#### IMMEDIATE RELIEF OF BURNS.

WE have already referred to the evidence afforded in American medical journals of the value of very strong solutions of bicarbonate of soda in the treatment of burns. In the *Louisville Medical News* for September 29th, Dr. Coleman Rogers records his experience in the treatment of burns by the application of soda, which is of value as corroborating the results claimed for such applications during the past year in the *Boston Medical and Surgical Journal*; and in the number of December 29th Dr. McClellan reports that, early in October of this year, a young female child was carried to his hospital suffering from a severe scald, which involved the hand and forearm of the right side. This child, when brought to the hospital, was in a terror of agony, and almost unmanageable. The injured arm was carefully wrapped in soft cotton cloth, which was soaked with a saturated solution of the bicarbonate of soda, and in a few moments the pain was entirely relieved and the child was sleeping. The use of the solution of soda was continued, no other treatment being necessary, and the convalescence was rapid.

#### MEDICAL MICROSCOPICAL SOCIETY.

IN accordance with a resolution passed at the special meeting of this Society on December 21st, 1877, the final meeting, for winding-up the Society's affairs, was held on January 18th, 1878; H. Power, Esq., President, in the Chair. The Committee's report was read by Mr. Groves, one of the secretaries; and the treasurer, Mr. T. C. White, presented the balance-sheet. The balance, which was but a small one, and to which were added the proceeds of the sale of the property of the Society, was unanimously voted to be equally divided between the two secretaries and the treasurer, in the form of a testimonial to each of these officers. The President then vacated the chair, and the Society ceased to exist.

#### PROFESSOR RANIERI BELLINI.

WE regret to learn, from a paragraph in *Lo Sperimentale* for January, that Dr. Ranieri Bellini, Professor of Toxicology and Forensic Medicine in the Royal Institute of Florence, committed suicide by poisoning on January 12th. The motive is said to have been an overwhelming fear that he had committed an act which would disgrace the honourable life which he had always led. Dr. Bellini, who was sixty years of age at the time of his death, had attained a high reputation as a teacher, and as a scientific investigator of the action of toxic substances. He published a valuable series of experiments on poisons in *Lo Sperimentale* for 1876. In conjunction with Dr. Filippi, he was the author of a *Biblioteca Medico-legale*, the third and concluding volume of which has just been completed.

#### THE USE OF DISINFECTANTS.

DR. W. O. BAYLIS, the accomplished Medical Officer of Health for West Kent, has issued some plain instructions for preventing the spread of infectious diseases, in a revised edition, as a little tract published by Knight and Co. On the vexed subject of the choice of

disinfectants, Dr. Baylis, who has, we believe, devoted much attention to this subject, gives detailed directions. He remarks that powdered green copperas, Condy's fluid, and chloralum, may be substituted for chloride of lime, ounce for ounce. For those, the stronger mixture No. 3 would be two ounces to the pint of water, and the weaker, as in No. 6, four ounces to the gallon. For carbolic acid, he says, Burnett's fluid may be substituted, the stronger solution only requiring one ounce to the pint; and the weaker, three ounces to the gallon. A good disinfectant, properly managed, is sulphur fumigation. For floors, walls, ceilings, etc., carbolic powder is "useful, and equally so are chloride of lime, carbolic powder, and powdered charcoal, for the outside of buildings. For mud ponds, or other wet foul masses, Ledger and Co.'s "Universal Disinfecting Powder", containing salts and metallic chlorides, Dr. Baylis is of opinion, promises the most effectual result.

#### LIQUEFACTION OF HYDROGEN.

ON January 10th, M. Pictet of Geneva performed, in the presence of many persons, the experiment of liquefaction of hydrogen. The process consisted in the decomposition of formiate of potash by caustic lye, by which pure hydrogen was produced. Thirty-five minutes after the commencement of the experiment, a pressure of 650 atmospheres was reached, at which point it remained for some minutes. The tap of the apparatus being now opened, a bluish jet escaped with a crackling sound, like that produced by the contact of water and red-hot iron. The jet then suddenly ceased; and it appeared as if a hail of solid bodies was thrown violently with a rattling noise on the ground. The tap having been again closed, the pressure fell from 370 atmospheres to 320, at which it stood for a few minutes, then rising to 325. When the tap was again turned, a jet again escaped, which underwent interruptions, showing that beyond doubt crystallisation had taken place in the interior of the tube. This was proved by the escape of the fluid hydrogen when the temperature was raised.

#### ITALIAN MEDICAL JOURNALS.

FROM a table published in the January number of the *Annali Universali di Medicina e Chirurgia*, we learn that there are twenty-nine medical journals in the kingdom of Italy. Of these, five are published in Milan, five in Naples, three in Rome, two in Bologna, one in Pisa, two in Palermo, one in Padua, one in Genoa, three in Turin, one in Venice, two in Florence, one in Forlì, one in Reggio Emilia, and one in Modena. The oldest journal is the *Annali Universali*, which has completed its sixty-third year. Next come the *Bullettino delle Scienze Mediche*, published by the Medico-Chirurgical Society of Bologna, which has attained forty-eight years; the *Giornale della Reale Accademia di Medicina* in Turin, and the *Raccoglitore Medico* (Forlì), each forty years old; Professor Polli's *Annali di Chimica applicata alla Medicina*, which is thirty-four years old; and *Lo Sperimentale*, which has completed thirty-one years. The youngest is the *Commentario Clinico* of Pisa, which first appeared in 1877.

## SCOTLAND.

IT has been decided to enlarge, by the addition of a new wing, the Home for the Relief of Incurables in the west of Scotland, at an estimated cost of £8,000. The Home has only been open a year or two, but it is found far too small to accommodate the increasing numbers of applicants.

THE Glasgow Eye Infirmary continues to do good work, as shown by the fifty-fourth annual report, which has appeared lately. During 1877, nearly eight thousand patients were treated, of whom upwards of two thousand remained under treatment at the end of the year. The number of indoor patients was five hundred and seventy-six, an excess over the previous twelve months of sixty-eight; the average number of beds occupied daily was forty-eight.

It is announced that the Marquis of Hartington, Lord Rector of the University of Edinburgh, has intimated a subscription of £530 towards the fund for extending the University buildings.

#### MILK-SUPPLY AND TYPHOID FEVER.

ATTENTION has recently been called in Glasgow, in a very striking manner, to the milk-supply, by the outbreak of typhoid fever which, as we stated a short time since, was most conclusively shown by the medical officer of health for the city to have been due to the use of polluted milk. This epidemic is now subsiding, no new case having appeared for a fortnight; this result being undoubtedly due to the energetic measures taken by the authorities. Last week, a largely attended meeting of influential persons was held, under the presidency of the Lord Provost, to consider what steps should be taken to secure a supply of pure milk for the city and suburbs. Dr. McCall Anderson, Dr. Fergus, and others, took part in the meeting. It was resolved, "That it is desirable that a general measure of legislation should be passed with regard to the regulation of milk-supply". In the view of the meeting, it was desirable that all dairies which directly or indirectly supply milk to towns, should be bound to register themselves with the local authority, and that shops for the retail selling of milk should be required to take out licences. These dairies and shops should be regularly and frequently inspected. A committee was appointed to carry out the object of the resolutions.

#### THE LIVINGSTONE MEMORIAL.

THE Livingstone Medical Missionary Memorial Institution in Edinburgh was inaugurated last week, in the presence of a large and influential company. The entire building is not yet quite complete, but the part of it which is to be used in connection with medical work is fully equipped and ready for occupation. The medical part of it consists of a consulting-room and dispensary, a house for a resident surgeon, and bed-rooms for a number of students. The dispensary work has been carried on for the past twelve months, while the new buildings have been in progress, in an adjacent building. The Institution has been erected and furnished at a cost of £10,000, raised by voluntary subscriptions.

#### THE HEALTH OF FORFAR.

At a meeting of the Forfar Police Commissioners held last week, there was produced the report of Dr. Murray, the Medical Officer to the Board of Health, which stated that the total number of deaths registered during 1877 was 288, or at the annual rate of between 16 and 17 per 1,000: the lowest death-rate since the Registration Act came into force. Towards the end of the year, scarlet fever appeared in two families, causing one death; but no fresh cases had been reported. About the beginning of December, a case of fever was reported to have occurred in a dairy in Dundee Loan. The medical attendant informed the reporter that the case was not one of infectious fever, and no precautions were taken to prevent the sale of the milk. Since that time, the reporter had been called to five cases of continued fever of a typhoid type in the same locality, and it turned out that all the five families were supplied with milk from that dairy. Other cases occurred at that dairy, and the milk supply had been stopped. The medical officer recommended that precautions be taken similar to those adopted in Glasgow.

#### LECTURES ON COOKERY TO MEDICAL STUDENTS.

ON Saturday last, Miss Dodds, of the Edinburgh School of Cookery, delivered a demonstration lecture on Sick-room Cookery to over a hundred medical students, in the Extranatural Class-room, Nicholson Square, Edinburgh. Mr. Chiene presided, and in introducing the lecturer, impressed upon the students the importance of a knowledge of sick-room cookery to medical men. Miss Dodds then proceeded with her lecture, during which she demonstrated the process of making beef-tea, white wine whey, restorative jelly, and a number of other foods for invalids. The lecture was attentively and closely followed,

and most of the students took notes. On the motion of Mr. Chiene, a hearty vote of thanks was accorded to the lecturer, whose first lecture had, he said, been a gratifying and unqualified success.

#### SANITARY PROTECTION ASSOCIATION.

A MOVE in the right direction has lately been taken in Edinburgh by the starting of a Sanitary Protection Association. This Association, which is being formed under the auspices of many of the leading professional men and citizens, has for its objects the following: "1. To provide its members, at moderate cost, with such advice and supervision as shall ensure the proper sanitary condition of their own dwellings; 2. To enable members to procure practical advice, on moderate terms, as to the best means of remedying defects in houses of the poorer classes in which they are interested; 3. To aid in improving the sanitary condition of the city by following such course as, in the opinion of the Council, may seem calculated to promote this object." The Association is not intended as a substitute for municipal inspection, and will not conflict with the public authorities, but will supplement their action; and it is not proposed that it should undertake the superintendence of houses while they are being built, or interfere in any way with the public system of sewers. To effect these objects, members are invited to enrol themselves, paying a guinea a year as contribution. For this they will be entitled to (1) a report by the engineer of the Association on the sanitary condition of a dwelling or property, with specific recommendations, if necessary, as to the improvement of drainage, water-supply, and ventilation; (2) the supervision of any alterations in the sanitary fittings, which may be carried out by the advice or with the approval of officers of the Association; (3) an annual inspection of premises by the engineer of the Association, with a report. The Association will secure the services of a consulting engineer and one or more resident engineers, whose whole time is to be devoted to the work of the Association. Both the consulting and the resident engineers are required to declare, on their appointment, that they have no interest in any patent or manufacture connected with sanitary appliances.

#### IRELAND.

DR. FITZGERALD, Surgeon-Oculist in Ordinary to the Queen in Ireland, has been appointed Examiner in Ophthalmic Surgery in the University of Dublin.

AT a recent meeting of the Clonmany Dispensary Committee, Dr. McCullough of Gortin was elected, by a majority of votes, medical officer to the district.

LAST week, in Belfast, a lady, whilst walking in her sleep, fell a considerable height, and died shortly afterwards from the injuries she had received.

#### DEATH OF DR. FLEETWOOD CHURCHILL.

WE regret to announce the death, on Thursday last, of Dr. Fleetwood Churchill, the late distinguished Professor of Midwifery in the School of Physic of the University of Dublin, and ex-President of the King and Queen's College of Physicians. Dr. Churchill retired from practice three years since, living in comparative retirement at the residence of his son-in-law in the County Tyrone. His illness was only of a few days' duration.

#### BELFAST HOSPITAL FOR SICK CHILDREN.

THE fifth annual meeting of the friends of this institution was held on Friday, the 25th ult., at Belfast. The report of the Committee showed that a satisfactory balance, close on nine hundred pounds, existed to the credit of the charity; and that more than £4,000 had been obtained for the construction of the new hospital, leaving about £860 to be collected in addition. Twenty memorial cots have been promised, and the Committee trust that, before the new building

is opened, as many more will be given as will completely furnish it. During the twelve months ending December 31st last, two hundred and seventy-seven in-patients and six thousand three hundred and sixty-three out-patients were prescribed for at the hospital; several serious operations were performed, none of which were attended with fatal results. The mortality among those admitted was very trifling, but four deaths having taken place. The amount realised by the late bazaar held in aid of the funds, after paying all expenses, was £1,512 16s. 8d., and a vote of thanks was passed to the Ladies' Committee for their efforts in connection with making the bazaar so successful. A vote of thanks was also accorded to the medical staff for the skilful and conscientious discharge of their onerous and responsible duties, after which the proceedings terminated.

#### TESTIMONIAL TO DR. GORDON OF BELFAST.

IT is intended by a number of this gentleman's former pupils and friends to present him with a testimonial, which, it is proposed, shall take the form of a portrait in oil. Subscriptions to the amount of nearly one hundred pounds have already been acknowledged towards the fund formed for this purpose. Dr. Gordon is Professor of Surgery in the Queen's College, Belfast, and is well known as an eminent surgeon. We may add that he is the inventor of the "keel"-shaped splint, which has proved so successful in the treatment of Colles' fracture.

#### THE ADELAIDE HOSPITAL.

MR. ALBERT WALSH, senior surgeon to this institution since its foundation, has resigned. Among the names of probable candidates for the vacant post, we hear mentioned Dr. C. B. Ball, at present chief surgeon to the Blaenavon Iron and Steel Company, South Wales; Mr. C. H. Robinson; Mr. William Stoker; Mr. H. J. Tweedy; and Mr. Montgomery A. Ward, the assistant-surgeon of the hospital. Owing to the extensive additions at present being made to the hospital, and the reduced numbers of beds consequently occupied during the progress of the necessary alterations in the main building, it is probable that the election of a surgeon in Mr. Walsh's room will not take place until next summer, when it is expected that all the works will have been completed. Her Grace the Duchess of Marlborough visited the hospital last Monday.

#### SLIGO WATER-SUPPLY.

AN important inquiry has been recently held by the Local Government Board into the mode of supplying water to this town, under the Public Health Act, 1874, promoted by the corporation to obtain a provisional order for that object. It appears that the corporation scheme was devised by Mr. Hassard, C.E., and promoted by them in 1867-69, being sanctioned by the Sligo Borough Improvement Act. For want of funds, the corporation did not carry it out, and allowed their powers under the Act to expire; and now sought for an order enabling them to borrow £40,000, to be paid in fifty years by a borough rate. The evidence for the corporation was to the effect that at present there was an insufficient supply of water to the town, and that that obtained from the pumps and wells, the only present available supply, was impure. The river Sligo could not be utilised, owing to its foul condition, it being contaminated by sewage and other causes. Mr. Hassard's scheme consists in impounding the waters of three streams which rise in the mountains about four miles from the town, at a height of from four hundred and fifty to nine hundred feet above the sea-level; collecting it in a reservoir covering thirteen acres, with an embankment and flood-courses annexed for carrying away the heavy floods, with waste-sluiques and other adjuncts. The water is then brought to a smaller reservoir about one hundred and sixty feet above the level of the sea and then delivered to the town. The water, being very pure, will not require filtering, and can be supplied at about one halfpenny per head of the population per week, at an estimate of £24,000. Those who opposed this scheme objected, first, to the site of the reservoir, as the strata in the beds of the streams and the valleys, being

firm, would be likely to permit the escape of the water stored up; and that the estimate was much higher than necessary, as a very much cheaper plan could be adopted by which water could be pumped up from Lough Gill, with a reservoir close to the town, at a cost of £8,000, the annual expense of steam-engines, coals, etc., being under £300. The inquiry lasted for four days, and the inspector's report has been forwarded to the Local Government Board for their consideration.

#### THE REGIUS PROFESSORSHIP OF PHYSIC.

CONSIDERABLE interest is felt among the members of the profession in Dublin as to the probable future occupant of this important chair in the University of Dublin. There are now three candidates for the appointment; viz., Dr. Hudson, the ex-President of the Dublin Branch of the Association, and Physician-in-Ordinary to the Queen in Ireland; Dr. Banks, the late King's Professor of the Practice of Medicine in the School of Physic; and Dr. William Moore, the present occupant of that chair. The election, which lies between Dr. Hudson and Dr. Banks, is virtually in the hands of the University Council. This body consists of sixteen members; and at their meeting on the 13th instant it will nominate to the Board of Trinity College the candidate on whom it may decide for the professorship. The emoluments of the office are, we believe, about £200 *per annum*.

#### CORK STREET FEVER HOSPITAL, DUBLIN.

DR. GRIMSHAW, having nearly completed his term of seven years' office as permanent physician to this hospital, retires, according to rule, on the 31st of March next; and Dr. J. W. Moore, one of the two temporary (honorary) physicians, becomes a permanent physician. An election of a temporary physician, *vice* Dr. J. W. Moore, was held last week. Dr. William Stoker was the successful candidate.

#### ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.

THE bazaar held last week in aid of the building fund of this hospital was a success; a sum of, we understand, nearly £200 being realised. Mr. Arthur H. Benson, M.B., has been appointed resident surgeon to the hospital.

#### DR. STEEVENS'S HOSPITAL.

WE are informed that Dr. Freke, senior physician to this hospital, has resigned. He will probably be succeeded by Dr. Bookey, who for many years has assiduously worked in connection with the hospital. Dr. Grimshaw, at present lecturer on *Materia Medica* in the medical school of the hospital, will, it is believed, succeed Dr. Freke as lecturer on the Practice of Medicine.

#### SANITARY CONDITION OF KINGSTOWN.

FROM the report of the Commissioners of this township, for the past year, it appears that the provisions of the Public Health Act, 1874, continue to be carried out. During that period, 3,121 houses and yards were inspected; 676 persons were noticed to make sanitary improvements; 445 nuisances were abated by service of notices; 241 persons were summoned to abate nuisances; 223 privies and ashpits were cleansed; 228 pigstyes and yards were cleansed, and the manure removed; 229 houses were lime-washed by the owners; 56 privies were put into proper repair; 22 branch sewers were constructed, and 26 were cleansed; 10 parties were fined for disobeying the orders of the magistrates; 9 notices were served upon the sanitary medical officers to inspect common lodging-houses; and the slaughter-houses were inspected weekly. During the past year, the extensive system of internal drainage, previously commenced, has been carried on without interruption and now approaches completion. The great outfall sewer, for a distance of 3,000 feet along the slopes of the west pier, for the purpose of conveying the sewage of all the western part of the township, and of an extensive district of the adjacent township of Blackrock, is nearly finished. A modification of the plans for this work has, with the approval of the Board of Works, been adopted; and a tender for the execution of this design, for the sum of £14,100, has been received.

## DUBLIN BRANCH: FIRST ANNUAL MEETING.

THE first annual meeting of the Dublin Branch was held on Wednesday last, January 30th, in the Hall of the King and Queen's College of Physicians; ALFRED HUDSON, M.D., Physician in Ordinary to the Queen in Ireland, President, in the Chair.

*Election of Members.*—Twenty-one gentlemen were elected members of the Association and of the Branch; and six members of the Association were elected members of the Branch.

*Report of Council.*—The following report was read by Dr. DUFFEY, the Honorary Secretary.

Your Council, in submitting their report to the first annual general meeting of the Dublin Branch of the British Medical Association, congratulate the members on the progress the Branch has made since its formation, and on the position it now occupies in the parent Association.

It has long since been recognised that a complete organisation, and a power of united and simultaneous action, were elements of the highest importance in furthering the interests of the medical profession. Only by the weight of such an organisation, at once extended and united, can expression be given on any necessary occasion to the common sentiment and opinion of the profession. Only thus can the public or the State be brought to feel the influence of professional judgment or opinion; for views entertained by isolated individuals remain unheard and unfelt, but, when expressed by united organisation, tell with overpowering weight. Such an organisation of our profession, beginning from a small and local origin, has within the last few years advanced to gigantic proportions. In its central unity and its local independence, it presents an agency which is most calculated to serve the common interest of our profession.

But in this organisation we, in Ireland, have hitherto had but little share. In this city—the capital and professional centre of the country—numerous as were the members of the British Medical Association, there has heretofore been no collective organisation in connection with it; and, hence, no common voice, no united weight in its management, not even individual representation on its Council. It seemed desirable that this should be changed. Accordingly, on the 15th of May last, starting from so small an origin as a private meeting at the house of the Honorary Secretary of the Association for Ireland, of less than a dozen members, the Dublin Branch was established, and on this day, under the most favourable auspices, holds its first annual general meeting.

The Branch was formally recognised by the Committee of Council of the Association, and its by-laws approved of, on July 11th, 1877. The following resolution, a copy of which was forwarded to your Honorary Secretary, was passed on this occasion:

“Resolved—That the warm congratulations of the Committee of Council be offered to the members in Dublin and the province of Leinster upon the successful formation of a Branch of the Association in the metropolis of Ireland. The Committee of Council trusts that it may be the means of strengthening the voice of the profession in Ireland, and of bringing the Irish members of the Association into closer connection with their Scotch and English brethren.”

Your Council would take this opportunity of thanking the leading members of the Association for their courteous recognition of the Branch, and especially the President of the Association, Dr. Wilkinson of Manchester, and Mr. Ernest Hart of London, the talented and able editor of the BRITISH MEDICAL JOURNAL, who have honoured us on this occasion with their presence and support.

It is a matter of much gratification to your Council that, in so short a time as seven months since its formation, the Dublin Branch now numbers one hundred and thirty-two members, and that no fewer than forty-four new members have been added to the Association through the instrumentality of our Branch. Our members include the leaders of the profession in this capital; while the interest taken by the professional corporations as such in the welfare of the Branch is evidenced by the fact that we are permitted to hold our meeting in this hall.

Three meetings of Council have been held since the formation of the Branch. At its first meeting, it provisionally appointed, as your representatives on the Council of the Association, your President Dr. Hudson, the Rev. Professor Haughton, Dr. McClintock, and Mr. Stokes. As the present number of members in the Branch entitle it to have seven representatives, your Council recommend that the same gentlemen, and, in addition, Mr. Porter, Dr. Hayden, and Dr. Ashe, be elected. Your President, three of your representatives on the Council, the Honorary Secretary, and several members of the Council and of the Branch, attended the annual meeting of the Association at Man-

chester, and were received with the greatest courtesy and hospitality by our English fellow-members. Your Council desire it to be emphatically understood that neither the British Medical Association, nor its branches, enter into rivalry or competition with the Irish Medical Association, to whose energy, zeal, and watchfulness the practitioners of Ireland owe so much. The objects of both Associations, though harmonising, are yet distinct. The special circumstances, conditions, and relations to the public of the profession in Ireland, render it essential that an Irish Association, specially conversant therewith, should specially act therein. The aim of this Branch is rather to co-operate with the profession in England and Scotland, as regards those National and Imperial interests which bear on the welfare of the profession in the three kingdoms alike—or rather throughout the entire British Empire, embracing at once also the Army, Navy, and Civil professional services, in its comprehensive consideration. Neither do we propose to interfere with the line of working of the various professional scientific societies of this city, but to confine ourselves to the general interests of the profession, and the cultivation among our members of a spirit of kindly intercourse, fraternity of feeling, and recognition of our common aims and interests. Our brethren in Cork have, through the energy of Dr. Macnaughton Jones, been before us in taking the step of organising a Branch of the British Medical Association for the South of Ireland, and have in gratifying terms expressed their pleasure at our following their good example. But we are pleased to find that our own example has been speedily followed by the formation of a Branch in Belfast, the commercial capital of the country, which embraces the important province of Ulster in its organisation: and we welcome with cordial gratification the presence of the Presidents of both these Branches with us to-day. The three most important and influential cities and provinces of Ireland have now accordingly obtained due weight and influence in that vast professional organisation, numbering at present over 7,000 members, the ramifications of which extend into every district of our United Empire. The influence of the British Medical Association, in uniting our profession for the furtherance of their common welfare and the interests of Medical Science, is only now beginning to be felt and understood. We cannot doubt but that it will widen and increase in extent and weight with each succeeding year, including alike the profession, and with it of necessity the public also, in its beneficent operation.

The adoption of this report was moved by Dr. JAMES LITTLE, Vice-President of the King and Queen's College of Physicians, and seconded by Mr. P. C. SMYLY, Vice-President of the Royal College of Surgeons in Ireland.

*President's Address.*—Dr. HUDSON delivered an address, which will appear in the next number of the BRITISH MEDICAL JOURNAL.

*Officers and Council.*—The following officers and Council for the ensuing year were balloted for and duly elected. *President:* George H. Porter, M.D. *President-elect:* Samuel Gordon, M.D. *Vice-Presidents:* Robert McDonnell, M.D., F.R.S.; Thomas Hayden, F.K.Q.C.P.I. *Council:* Isaac Ashe, M.B.; Lombe Athill, M.D.; Edward Bennett, M.D.; Thomas Darby, F.R.C.S.I.; T. W. Grimshaw, M.D.; Edward Hamilton, M.D.; Rev. Samuel Haughton, M.D., F.R.S.; Henry H. Head, M.D.; Alfred Hudson, M.D.; Edward Mapother, M.D.; Alfred H. McClintock, M.D.; William Stokes, M.D. *Honorary Secretary and Treasurer:* George F. Duffey, M.D.

*Votes of Thanks.*—A warm vote of thanks to Dr. Hudson, for his admirable address and for his services in the office of President, was proposed by Dr. GORDON (President of the King and Queen's College of Physicians), seconded by Dr. MCCLINTOCK, and carried by acclamation.

A vote of thanks was also given, with much warmth and cordiality, to Dr. Duffey, the Honorary Secretary, to whose services in organising the Branch a just tribute was paid.

*Dinner.*—In the evening, a dinner was held at the Hall of the King and Queen's College of Physicians, under the presidency of Mr. Porter, Surgeon to the Queen in Ireland, at which a numerous and influential company was assembled, and at which speeches of great interest were delivered in connection with the status and development of the Association in Ireland.

Our Dublin correspondent telegraphs: The dinner following the meeting was a highly successful and interesting event, and cannot fail to exert an important influence on the interests of the Association in Ireland. Mr. Porter, Surgeon to the Queen in Ireland, was in the chair; and eighty members and visitors sat down, including leading representatives of all departments of medicine and surgery and of the official bodies; the President of the British Medical Association (Dr.

Eason Wilkinson); the Editor of the BRITISH MEDICAL JOURNAL; the Presidents of the Northern and Southern Branches of Ireland and of the Irish Medical Association. Congratulations and favourable anticipations were expressed on all sides.

We hope to publish next week a full report of the event, which auspiciously renews and consolidates the bond of connection of the Association in Ireland.

The Board of Trinity College invited the President, the Honorary Secretary, and the leading visitors to dinner in the Hall of the College on Thursday. This recognition of the Branch is highly appreciated.

#### PROFESSOR HUXLEY ON WILLIAM HARVEY.

ON Friday, the 25th ult., Professor Huxley delivered a lecture, to a very large audience at the Royal Institution, on William Harvey. The lecturer commenced by saying that on the 1st of April next exactly three hundred years would have elapsed from the birth of William Harvey, who, he imagined, was best known to his hearers as the discoverer of the circulation of blood; although, in truth, this was only one of several claims which he had to the consideration and reverence of his successors. In popular repute, however, there was much diversity of opinion as to the precise share of merit attributable to Harvey in regard to this most important discovery. So much obscurity had been thrown about that question, partly by design and partly unintentionally, that he could possibly render no better service than by endeavouring to clear up the question to some extent, or at any rate adding his mite to that end. Were he fortunate enough to be dealing with an astronomical subject, there would be there few who did not know something of the earth's movements round the sun; but he must not suppose them to be familiar with the elementary facts of the circulation of the blood. It would, therefore, be expedient for him to place before the audience briefly the facts which constituted what was known and understood of the doctrine of the circulation of the blood, afterwards to consider the statements he made, and finally to add a few words respecting the method which led Harvey's predecessors and Harvey himself to make their investigations successfully. The doctrine of the circulation of the blood had four main elements: first, knowledge of the structures in which that circulation takes place; secondly, a knowledge of that which is contained in those structures; thirdly, a knowledge of how that which is contained moves; and lastly, a knowledge of the cause of the movement.

The lecturer then proceeded, by the aid of explanatory diagrams, to describe the heart, its organisation and its function. Treating of the gradual advance which human knowledge had made, he observed that, in tracing back the history of this doctrine, the student was led back to Grecian learning. Turning to the works which were published under the name of Aristotle, in the fourth century before Christ, and which formed a sort of encyclopædia of extant scientific knowledge, it was found that the structure of the heart was understood, and what were sometimes stigmatised as blunders were really mere errors of description. About 300 B.C., in the famous school at Alexandria, there arose a body of scientific anatomists, amongst whom there were two (Hieroctes and Aristippus), the amount of whose knowledge that had come down to us was very considerable; the last understood the mechanical operation of the valves. Reference was then made to the extraordinary genius of Galen, and Professor Huxley pointed out that his mistake in assuming that there was a perforation between the right and left sides of the heart led him away from the track of the discovery of the circulation of the blood, and threw physiology wrong for a great number of years. For thirteen hundred years from the death of Galen, no advance was made. Political and social troubles caused the works of Galen and his school to take refuge among the Arabians; they were brought back into European learning through the agency of the Moors, who settled in Spain and elsewhere, and by people who had travelled in Moorish countries. The next advance was that made by Servetus, who was judicially murdered by John Calvin, who, being a thorough-going man, burnt Servetus's works as well as himself, and thus the real worth of any claim to the discovery which might be made by Servetus would never be known.

After touching on the theories of Rualdus Columbus and Ambrose

Paré, and the claims of Spigelius, who, he said, must have been a fellow-student of Harvey, and who did not get as far as Galen and Columbus, he described the propounding of Harvey's theory in 1619, and the publication of his pamphlet in 1638. This, he said, caused a perfect revolution. So far as the anatomy of the organ was concerned, it left matters where they were; but, as regarded the motion of the blood, Harvey gave the most complete demonstration; and the lecturer pointed out that to Harvey alone could be given the credit of the discovery. One thing Harvey could not do, because the instruments of the time would not enable him to do it: he never gave the exact channels by which the blood passes into the veins. The evidence of the magnitude of Harvey's discovery would be seen by looking into contemporary literature. They would there find, in the persistence and virulence of the attacks made upon him, that he was introducing some considerable new truth. Riolan, a Parisian professor of anatomy, was quoted as an example of this. Within thirty years of the promulgation of Harvey's views, all had come round to his side. Thomas Illogg said Harvey was the only man who had the good fortune to see the doctrine which he propounded accepted in his own lifetime. He (the lecturer) could not but be struck, in looking at those old documents, to find how history in our days repeats itself. There was another controversy familiar of late years in regard to Darwin's views, in which the same things were said; but he thought Darwin would be the second man living long enough to see the doctrine now so abused and derided accepted by the leaders of science throughout the civilised world.

He had promised to say something as to the methods of investigation. Englishmen had sundry superstitions; among them, none more curious, more wide-spread, more deeply rooted, than that which led them to speak of Sir Francis Bacon, some time Lord Chancellor of England, as the father of modern science. Bacon was a contemporary of Harvey, who is said to have attended him in a medical capacity. Harvey's work was done by the year 1619; but the *Novum Organum* was not published until 1630. That was something against Bacon's being the father of that particular branch of science. Nor was there in Harvey's work the smallest trace of the writings of Bacon. If there was one thing which distinguished Harvey more than another, it was the invariable respect and reverence he paid to his predecessors in scientific discovery. Bacon's works were characterised by contrary traits; he saw nothing of importance either in the discoveries of the ancients or in those of his contemporaries. Harvey's method was the method of any man who did any good scientific work; it was simply common sense refined and made exact. For three thousand years, scientific investigation had gone off the track for no other reason than neglect of observation and experiment. By no possibility could the action of living things be inferred from the action of dead parts. It followed as a necessary consequence, that the only basis of physiological science was observation and direct experiment on the organs in the living state. There was no more instructive history than the history of the circulation of the blood in that respect. It would be found that the progress of discovery had been in exact proportion to the practice of experiment and observation on living objects. It must be so; there was no other way in which the necessary facts could be ascertained. The whole of history taught us that the advance of knowledge was only possible and practicable by direct observation; and there could be no doubt that Harvey's discovery was made by observing the course of the blood in the living animal. The observation was a simple one, and could be repeated, with all possible care that the animal should be insensible. Nevertheless, if any English subject at this time should repeat it, and if it so happened that such a monstrous state of things should exist that the affairs of the Home Office passed into the hands of a minister less wise and less steady in resisting all sorts of pressure, both legitimate and illegitimate, than the present one, the person who made that experiment might be punished as a common malefactor.

He did not propose to trespass upon the burning question of vivisection; he had already expressed his views upon it where he was responsible for them. There might be some who thought it would be better that the whole human race should perish than that a dog should suffer. It might be said, on the other hand, that those who would not save a human life by the destruction of a whole hecatomb of animals were guilty of constructive murder. He wished to make one or two observations, not to trench upon a dangerous neighbourhood, but to clear the ground. He begged his audience to look into the history of physiological science as they had investigated the history of the circulation of the blood; and, when they had investigated it, to tell him of any cardinal truth in physiology which did not rest upon, and had not been established exactly as Harvey's was established by, repeated experimentation. The lecturer was quite aware that it was said, on

the authority of Robert Boyle, that Harvey made the discovery of the circulation of the blood, reasoning deductively by the action of the blood in the veins. He replied, that the words of Robert Boyle did not bear out his conclusion; that the words of Harvey did not bear out the statement; and, if they did, nevertheless it was an error, for it was logically impossible to discover from the action or from the structure of the dead valves, what the functions of those parts might be when in a state of activity. He would not trouble his audience by reading the extracts which he had prepared from Harvey, which gave an interesting account of the course that led him to establish the doctrine of the circulation, but would ask them to take his word for it that there was not a word to bear out the statement of Boyle.

Another consideration which he would suggest was possibly one personal to himself. He had been credibly informed that there was no more thorough sign of approaching senility than to be a "laudator temporis acti" [laughter]; yet he would like to suggest that the things which happened in the seventeenth century were somewhat different from what happen now: the contrast was worthy of consideration. Harvey was the favoured friend of his sovereign; he was the honoured Nestor of his profession; he was a man who was looked up to by all of his countrymen as a person of whom they had every right to be proud. That was what happened in the seventeenth century. But if Harvey lived in these days, and had made the mistake of conferring the same vast benefit on mankind as he did then, he assuredly would receive no such marks of favour. Probably, to its honour be it said, his profession would honour him as much now as it did then; but he would find that a very considerable proportion of the general public would not give him marks of favour, but would make him a mark for quite another sort of thing, a mark for envious vituperation and abuse. He would find a considerable proportion of all classes of the community, whose sole object in life would be, if possible, to confer on him the legal status of a burglar. [Laughter.] The time of Harvey was, he need not tell them, one of the most remarkable periods in English history. Harvey might have conversed with Hobbes, Locke, Newton, with Strafford, and with Cromwell. Now, in that day those men illustrated the power of the English race in a manner like which it has never been illustrated before or since; and he would just suggest whether it was possible that their judgment on the moral and social question might possibly have had as good foundation as that of the people in this refined, enlightened, and, he might add, softly sentimental time.

### THE LATE DR. WILLIAM STOKES.

WE have the satisfaction of presenting to our Associates this week a portrait of the late eminent and esteemed Regius Professor of Physic in the University of Dublin. It is taken from a photograph in the possession of Dr. Samuel Gordon, kindly lent by him for the purpose. The engraving will be recognised by all who knew Dr. Stokes as a faithful representation of his features; and we have no doubt that it will be valued by very many members of the Association as a memorial of one of the greatest masters in medicine and one of the brightest ornaments of his profession.

Two interesting notices of Dr. Stokes lie before us. One, from the pen of Dr. J. W. Moore, appears in the *Dublin Journal of Medical Science* for this month, and ably reviews his professional life and works. His character is thus summed up at the end of the article. "A model and diligent student, he in time became a painstaking and successful teacher—the sympathising friend, the prudent counsellor, and the ardent well-wisher of every one of his 'fellow-students', for so he called his pupils. But he was more than this. Those who have seen Dr. Stokes at the bedside of the sick know how gentle, how refined, how kindly was his bearing towards the patient. Amid all the ardour of clinical observation and research, he never for one moment forgot the sufferer before him; no thoughtless word from his lips, no rough or unkind action, ever ruffled the calm confidence reposed in him by those who sought his skill and care. In many eloquent lectures delivered in the Meath Hospital, he inculcated these Christian lessons of charity and thoughtfulness; and so by precept and example, he strove to teach the duties of a true and God-fearing physician."

The other article to which we have referred is one in *Macmillan's Magazine* for February, entitled "Dr. William Stokes of Dublin: a Personal Sketch: by the Rev. J. P. Mahaffy." In it the author speaks of Dr. Stokes as he appeared in his extraprofessional life, and shows how this hardworking and grave physician was one of the most pleasant and genial of companions.

An interesting memoir of him was also published in the *Dublin University Magazine* for August 1874, with a portrait; which, however, represents him in younger days.

We commend all these memoirs to our readers for attentive perusal.

### UNIVERSITY OF OXFORD.

A "STATEMENT of the Requirements of the University, adopted by the Hebdomadal Council on the 19th of March 1877, with the Papers upon which it was founded", contains the following document by Dr. Acland, dated May 11th, 1876.

1. I assume that we are only to undertake at present the preliminary scientific studies at the foundation of medicine, and not to found now a complete practical school. The reasons are stated in a former communication.

2. For this purpose, I should retain the office of the Regius Professorship of Medicine as at present. (Though I should not advise limiting or defining his department of study, he might, in the present state of knowledge, study with advantage the results of observations on national health in the various countries and races of the world. I have begun a collection of books on this extensive subject in the Radcliffe Library, as the groundwork of comparative study of the health-conditions of nations. This subject is but "hygiene" in its widest sense.)

3. The Regius Professor should have the assistance of an analyst and demonstrator of medical and sanitary chemistry and microscopy. (Mr. Denkin, Dr. Pöde, and Von Bose have filled this office for several years in the Sanitary Laboratory of the Museum, wholly unpaid by the University.)

4. I would add a professor or lecturer on general and comparative pathology, i.e., the fundamental laws of abnormal change in man and animals. This is complementary to the teaching of normal physiology, and is closely allied to the department of hygiene as described above. (He need not be resident, and should be appointed for not more than five years. The funds of the Clinical Professorship would be a foundation for this.)

5. The Professor should have a sum of money at his disposal, subject to the approval (say) of the Vice-Chancellor, to engage an eminent lecturer on special subjects, to illustrate the connection of the fundamental sciences with medicine; as, for example, the combined results of mathematics, physics, physiology, pathology, and therapeutics in the investigation of the organ and function of vision.

HENRY W. ACLAND.

### HYDROPHOBIA AND RABIES.

THE Committee recently appointed by the Scientific Grants Committee of the British Medical Association "to organise an inquiry into the Causation, Pathology, and Treatment of Rabies and Hydrophobia", consisting of Mr. Callender, F.R.S., Dr. Burdon Sanderson, F.R.S., Dr. T. Lauder Brunton, F.R.S., Mr. Ernest Hart, and Dr. Gowers, desire to announce that they will feel favoured if any medical gentleman having under his care a case of hydrophobia will kindly communicate with them. In any cases of hydrophobia or of rabies in which a *post mortem* examination is made, they will be glad to receive for investigation the following parts; namely, the spinal cord, medulla oblongata and pons Varolii, a small piece of the cerebellum, corpus striatum, convolutions of the middle third of the brain, one of the salivary glands, the nerves leading to the part bitten, portion of the liver and of the kidneys, and the scar. These should be at once placed in a mixture of equal parts of spirit and water (or, if the organs be at all softened by commencing decomposition, in a mixture of three parts of spirit to two parts of water), and forwarded with as little delay as possible, together with a report of the *post mortem* appearances, to the Office of the British Medical Association, 36, Great Queen Street, London, W.C.

The members of the Committee are also anxious to have the opportunity of visiting cases of hydrophobia under treatment, or of attending any *post mortem* examinations in fatal cases.

MR. W. WATERS, Deputy-Coroner for Hants, conducted an inquiry on Saturday at Kingsley, near Alton, on the body of a boy aged seven years, named Aaron Dawes. It appeared from the evidence that, whilst playing with two other boys in a meadow, a sheep-dog bit him in the right hand. The dog subsequently strayed to a neighbouring village, where it bit a man, who at once shot the animal. The mother of the deceased washed the small wound which had been made by the bite,

and it soon healed. The deceased went to school until the 23rd ult., when he was taken ill. His symptoms became so alarming that Dr. Woods of Headley was called in, and he at once pronounced the case one of acute hydrophobia. The deceased died on the following morning in convulsions. The jury returned a verdict of "Death from hydrophobia".

#### THE BRITISH MEDICAL ASSOCIATION MEDAL FOR DISTINGUISHED MERIT.

As was stated in the JOURNAL of January 12th, the distribution of the medals of the British Medical Association to the medical men who had assisted in the rescue of the miners at the colliery accident near Pont-y-pridd last year, took place at the Grosvenor Restaurant in New Bond Street on January 9th.

The President and many members of the Committee of Council, with several invited guests, including all the medallists but one, having assembled before dinner, the presentation of the medals was made, after a few appropriate remarks, by Dr. EASON WILKINSON, President of the Association; who, as each gentleman was called up to him, placed the blue ribbon suspending the medal round his neck. The recipients of the medals were:

*Gold Medal:* Henry Naunton Davies, L.R.C.P., Cymer, Pont-y-pridd.

*Silver Medals:* Edward W. S. Davis, M.R.C.S., Mountain Ash, Aberdare; W. Washington David, Esq., Guy's Hospital; and Edgar Dukes, Esq., Cymer.

*Bronze Medals:* Rees Hopkins, L.R.C.P.Ed., Pont-y-pridd; Philip James, Esq., Guy's Hospital; Charles J. Jones, L.R.C.P., Pandy, Pont-y-pridd; Ivor Ajax Lewis, L.R.C.P.Ed., Llantrisant; Edward Lloyd, M.D., Miskin Manor, Llantrisant; George Neal, Esq., Pen-y-graig, Pont-y-pridd; Thomas W. Parry, L.R.C.P.Ed., Ferndale; and Francis H. Thompson, M.R.C.S., Gilfach-Goch, Llantrisant.

The medal is represented of the exact size in the accompanying drawings.

At the dinner, the chair was occupied by Dr. R. W. FALCONER, President of the Council of the Association. Besides the medallists, several guests, including Mr. Ernest Hart, Mr. Sibley (President of

the Metropolitan Counties Branch), Dr. Andrew Clark (President-elect), Dr. Henry (Secretary of the Branch), and other gentlemen, were present by invitation of the Committee of Council.

After the dinner, the CHAIRMAN proposed "The Queen", which was loyally received.

The CHAIRMAN then proposed the health of the medallists. He referred to the circumstances which had led to the institution of the medal by the adoption of a proposal made to the Committee of Council by Dr. Sieveking and Mr. Callender. The medical men were the only persons actively concerned in the rescue of the miners at Ty Newydd whose services had not received public recognition; and the medal of the Association was instituted to remedy such omission, and to show the value which their medical brethren set on such labours as those of Mr. Davies and the gentlemen associated with him. He congratulated the recipients of the medal on the recognition that they had met with from the Association; and trusted it would be an encouragement to them in the labours of their calling. He understood that, among the silver medallists, were two gentlemen (Messrs. Dukes and David) who had not yet entered on the active duties of the medical profession, being still students in medicine; and he congratulated them on receiving the medal thus early in their professional life. He hoped that the medal would not be given too often, but that it would be reserved for deeds of high merit such as that which had called it into existence. Its value would be endangered by too frequent award.

Mr. H. NAUNTON DAVIES said: I thank you most cordially for the honour you have conferred upon us, and for your kind invitation to be your guests this evening. At the memorable inundation of the Ty Newydd Colliery, we were called upon during those days and nights of deep anxiety and peril to share the dangers incident to the position; and we only claim to have done what I have no doubt every member of the profession would have done under similar circumstances—our duty. Her Most Gracious Majesty the Queen, sympathising as she always does with the affliction of even the meanest of her subjects, and desirous of marking her special favour to those who, at the risk of their

lives, had striven to extricate those poor men from their living tomb, caused the Albert Order to be extended from perils by sea to perils by land. We alone, the members of this profession, were excluded. The Council of this influential and powerful Society has rectified the omission; and the noble way in which you have done this deserves the warmest

thanks of the whole profession. For myself and those who are with me, and from whom I received the heartiest co-operation, I can only say I shall ever esteem it an honour, and I hope to hand this medal to my children, as a token of the honourable recognition of my profession for discharging the duties that fell to my lot. I again thank you for the high compliment you have paid me.

Mr. E. W. S. DAVIS said: I have to offer you, on behalf of myself and the other silver medallists, our most sincere thanks for the kindness you have shown us in drinking our healths, and the distinguished honour you have conferred upon us in the presentation of such handsome medals. I can safely say that, in following our professional duties at Ty Newydd, neither of us dreamed of being so highly distinguished. I had myself never been down a coal-pit before, nor slept all night in a shed waiting for action; but it was my duty to do both, and the reward has been too great. That my brother medallists worked with a will and in danger, sparing themselves nothing, I had ocular proof in the mine; for one, when I could recognise his features, had the aspect of the very dirtiest scarecrow I ever saw; while another had the appearance of an Ethiopian at St. James's Hall. Yet all worked nobly and well. Before leaving home to attend this meeting, it was my privilege, as medical attendant in the family of my distinguished neighbour and kind friend Lord Aberdare, to have the opportunity I desired of ascertaining from his lordship the relation in which the medical men stood with regard to the recipients of the Albert Medal in his lordship's most careful and scrupulous report to Her Majesty's Government. Lord Aberdare kindly read to me this report, and explained to me that the investigation required the utmost circumspection and care to be used in carrying out the specifications of the Royal Warrant. His lordship had been most desirous of its being made public, but the governing powers had considered it inexpedient, and that great inconvenience would accrue from such a precedent having been made. But it was permitted his lordship to embody any of his suggestions made in his address at Pontypriid when distributing the Albert Medal. In this address, Lord Aberdare makes honourable mention of several engineers and others (who, although working heroically and well, yet did not come within the particular desiderata of the Royal Warrant), and adds as follows: "In the same class I may fairly include Mr. Dukes, assistant-surgeon to Dr. Henry Naunton Davies, who went to the barrier at half-past five A.M. on Friday, when the danger was at its highest, in order to convey food to the imprisoned men." Gentlemen, I think the profession will be glad to know how near the Albert Medal one of us was. On behalf of myself and the other medallists, I return you our grateful thanks for the honour you have done us. This honour has come to me in the decline of my professional life, and in the commencement of it in others; but all are suitably impressed by the kindness and honours conferred on us by you this evening.

Mr. EDGAR DUKES said: I will not detain you a moment beyond expressing my deep sense of the honour done me in the presentation of this ever-to-be-prized medal, and the compliment paid by your kind invitation of this evening. I should like, in addition to the remarks of Mr. Edward Davis, to say that there was no Edgar Dukes in that mine; it was Wm. Washington David and Edgar Dukes. Where the one was the other was. We went together, we came together; we were together from first to last. Hence, whatever the one merited surely the other equally did. Thanking Mr. Edward Davis for coupling my name with the Albert Medal, I will only add that its value would have been very greatly deteriorated had not my friend shared the honour with me.

Dr. E. LLOYD said: I rise with great diffidence, blushing from my new-made honours—[a laugh]—to return you my best thanks for the distinguished honour you have conferred upon us, not only by enrolling us on your newly created order of merit, but also for the medals we have received at your hands, and for this handsome entertainment which you have so hospitably provided.

Sir, we are all interested in the recognition of merit wherever it may be found; and, in conferring the gold medal of your distinguished Association on my esteemed friend and former pupil, Mr. H. Naunton Davies, you have bestowed it on one who, from his earliest years, has distinguished himself by his devotion to his science, and who has raised himself to a very high position in the profession in South Wales, not only by his industry, skill, and judgment, but also by his modesty, courtesy, and conduct.

In the performance of the duties which fell to the lot of Mr. Davies and ourselves, on the occasion of the entombment of the colliers in the Ty Newydd Pit, we simply claim to have done our duty under the trying and dangerous circumstances in which we were placed; and I see before me two gentlemen, his assistants (Mr. Dukes and Mr. David), who, day by day and night by night, shared all the dangers

incident to the situation, in common with the colliers, engineers, and other workmen. But, gentlemen, they only did their duty; they expected no rewards; they only hoped to be of service to their poor suffering entombed fellow-creatures, as each of you would have done had you been in their place.

Gentlemen, we are all baptised into the service of humanity; but in our profession there are no rewards. Perhaps, in the term of a generation, five baronets may be made, selected chiefly for their attendance on important members of the Court or other distinguished personages. The State does nothing for our profession. In the sciences of chemistry, electricity, and hygiene, vast benefits have been conferred on the whole human race. Has our profession done nothing in these three departments, that it has received no rewards? Are there no names dear to science and to us that deserve recognition? Where are they to be found in the rolls of the orders of merit?

We have the satisfaction of knowing that our profession, whether in the battlefield, the sea-fight, or the bedside—in plague, pestilence, and death—has done its duty. The State recognises the services of the law by judgeships, baronies, and earldoms. Engineers, soldiers, sailors, diplomats, expect their well-deserved rewards and honours. For us there is no blue ribbon! Our consciences are our own rewards. It has been left to your noble Association, composed of 7,000 fellow-members of the profession, to establish an order of merit to which you have this day admitted us, and for this initiative you deserve the thanks of the whole profession. I desire to speak with every respect of those venerable bodies the Colleges of Physicians and Surgeons; but I would ask how long should we have waited before they would have recognised the humble merits of a few remote surgeons, who, in a deep pit in South Wales, spent eight days and nights waiting to assist some poor buried colliers? No, sir: "Palmam qui meruit ferat". To you belongs this honour, and for this we humbly return our thanks; and, for being made members of the order of merit, an honour which you have established, we shall ever esteem as the greatest we have received, except only from the fountain of honour itself—Her Most Gracious Majesty the Queen.

Dr. HOPKINS said that, suffering from travelling all night to attend the meeting, he could but express his thanks for the honour done him, and regret he was not well enough to say as much as he desired.

Dr. LLOYD proposed the health of Dr. Sieveking, to whom, with Mr. Callender, the institution of the medal was due.

Dr. SIEVEKING returned thanks for the honour done him. He said that the foundation of the medal for distinguished merit inaugurated a new era in the history of the profession of this country and of the British Medical Association. Public honours were rarely awarded to medical men, who did more work without fee or reward, and who had a larger share in the advancement of modern civilisation, than any other class of men. The case of the medical men who assisted in the Pontypriid accident was a glaring one of public neglect and slight. Without the moral aid given by the medical men, and by the encouragement afforded by their presence in the gloom of the mines, the labouring men would never have persevered in their arduous endeavours. The medical men, led by their brave chief, Mr. H. N. Davies, animated them to endure to the last, and success was mainly due to the doctors—to men who had no other motive to prompt them but that of the highest and most unselfish duty.

The health of the Chairman having been proposed and responded to, the proceedings terminated.

## THE HEALTH OF THE NAVY.

THE annual statistical report of the health of the navy has just been presented to the Board of Admiralty by the Director-General of the Medical Department, Sir Alexander Armstrong, K.C.B.; and its most encouraging feature is that, although on the total force employed during the year 1876 there was an increased sick-rate, yet in the death-rate from disease alone there was a reduction of 1 per 1,000, while the total death-rate was 1.44 below the average of the past thirteen years. The sick-rate, or number of separate entries on the sick-list, although higher than in 1875, was much below the thirteen years' average, there being a reduction of 41.81 per 1,000 of force. The invaliding-rate was rather higher than the thirteen years' average. In the introductory statement, which bears the signature of Deputy Inspector-General T. R. Pickthorn, as the successor of the late Deputy Inspector-General Mackay, testimony is borne to the continued advantages derived from the operation of the Contagious Diseases Acts on the Home Station as seen in the maintenance of a reduced sick-rate from those diseases; and a very important series of tables is given in the appendix to the report, contrasting the state of affairs in Her

Majesty's ships at five home ports where the Acts are in force with five home ports where they are not in force, the tables being spread over a period including three years before the Acts were passed. "These tables," the Deputy Inspector-General says—and the figures amply bear out his assertion—"show conclusively the benefits resulting from the legislation of 1864, 1866, and 1869, even in its present limited application". As regards the general medical history of the navy during the year under review, it appears that the force employed in the service afloat numbered 45,010, of whom 23,620, or 52.47 per cent., were between fifteen and twenty-five years of age; 14,430, or 32.09 per cent., between twenty-five and thirty-five; 5,640, or 12.53 per cent., between thirty-five and forty-five; and 1,320, or about 3 per cent., over forty-five. Of the total persons invalided, 50 per cent. were under twenty-five; 30 per cent. between twenty-five and thirty-five; 15.58 in the next decennial age period; and 4.27 above forty-five. The percentage of deaths in the first age period of service (fifteen to twenty-five) was lower than that of the invaliding; but still out of every hundred deaths, 40 per cent. were between fifteen and twenty-five, 31 per cent. between twenty-five and thirty-five, 21 per cent. in the third period, and 7 per cent. above forty-five. Of the total invalidings, more than one-fifth were due to diseases of the nervous system, and the loss of service from these diseases is stated to be increasing. Diseases of the digestive system caused 12 per cent. of the invalidings; phthisis or consumption, 11 per cent.; diseases of the circulatory system, 10 per cent.; and wounds and injuries, 9 per cent. Of the deaths at all periods of life, wounds and injuries were as usual the most prolific cause; but in 1876, the mortality was exceptionally heavy, the explosion in the *Thunderer* causing no fewer than thirty-five deaths in persons belonging to the service afloat; while there was also an increase in the deaths from accidental drowning. The disease which formed the most fatal factor in the death-rate was phthisis. No disease appears to have been epidemic either at home or abroad during the year, except small-pox at Bombay, the spread of which was checked by preventive measures. There were several cases of scarlet fever in a single ship in the Mediterranean, three cases of yellow fever in a ship lying at Barbadoes, an outbreak of influenza on the Pacific station, dysentery on the China station (during the operations on the Perak river), and scurvy was present on the Arctic expedition. A brief but succinct account is given under the head of the Irregular Force as to the health of the crews of the Arctic vessels, the opinion expressed by the Deputy Inspector-General being that "in considering the origin of this serious outbreak, it is not possible to escape from the conclusion that its primary cause was the omission from the dietary of the sledging parties of a sufficient supply of the antiscorbutic elements of food. No limejuice was included in the dietary, and the quantity of preserved potato and other vegetables carried was very small". It is further added, in confirmation of this view, that "the antiscorbutics with which the ships had been supplied were amply sufficient to effect a rapid cure of the disease after the men's return, and on September 8th, when the ships left the ice, there was not a single person on the sick-list of the ships".

#### AMENDMENT OF THE MEDICAL ACT.

DR. LUSH has reintroduced into the House of Commons the Bill of last year for amending the penal clauses of the Medical Act. We understand that Government has consulted the General Medical Council, and will probably introduce a measure having a wider range, including provision for uniform minimum examinations by conjoint boards in the three divisions of the Kingdom; amendment of the penal clause; provision for registering foreign and colonial degrees under the supervision of the Medical Council, etc. The outline of this Bill is to be found in the report of the proceedings of the Medical Council during the session of last year.

#### HOSPITAL AND DISPENSARY MANAGEMENT.

##### PROVIDENT DISPENSARIES IN BIRMINGHAM.

THE Committee of the Birmingham Provident Dispensaries have discovered at last the impossibility of establishing a dispensary without consideration to the wishes of the profession. At a public meeting held in the Town Hall in July last, a Committee was appointed, "with power to add to their number, to establish provident dispensaries in Birmingham and the district". This Committee consisted of forty-one members, and included eight aldermen or town councillors, nine clergymen or ministers of religion, but only three members of the medical profession, each of whom was a hospital surgeon engaged in consulting-

practice. At the annual meeting of the Birmingham and Midland Counties Branch of the Association, held on June 28th last, the following resolution was carried unanimously: "That, in the opinion of this meeting, the introduction of the provident dispensary system offers the best means of checking the excessive increase of the amount of gratuitous medical advice dispensed by our local charities; and that the Council of the Branch be requested to take steps for promoting the formation of provident dispensaries in the town." A copy of this resolution was conveyed to the Mayor, who was the convener of the Town Hall meeting, and a member of the Committee there appointed for the establishment of dispensaries, in a courteous letter written by the Secretaries of the Branch, of which the following is an abstract: "Our Society is the largest representative body of the medical profession in the midland counties, and a very general feeling prevails amongst its members that the provident dispensary system of medical relief, which is already in existence here, can only be fairly remodelled and prudently extended after very careful inquiry. The interests and position of existing provident societies, the customs, necessities, and means of the artisan population, and the legitimate requirements and views of the medical profession are equally deserving of consideration. Our Council, while pursuing the task entrusted to it, will be happy to give their best attention to any suggestion for co-operation which may emanate from any society or committee having the same objects in view." This opportune and considerate offer of co-operation was acknowledged, but it has never been acted upon. The lay committee on provident dispensaries went on with their work, without taking counsel with the medical profession; and they published about a fortnight ago their scheme of rules for the Birmingham dispensaries. This scheme is embodied in a pamphlet of ten pages. Among other regulations, the scheme proposes that "all persons", without regard to their means or state of health, "shall be entitled to be registered as members"; and, further, that "no stipendiary officer", that is, the surgeons amongst others, "of the dispensary shall be eligible, either as a member of the general committee of management or of the local committee". The Town Hall Committee decided that the first dispensary should be established at Hockley, and that it should begin with a staff of four surgeons; the honorary secretary of the committee, an Unitarian minister, thereupon visited three members of the Birmingham Branch of the Association, and proposed that they should become surgeons to the projected dispensary. Those gentlemen declined to accept office under the existing scheme, and they and some of their medical brethren requested the Council of the local Branch to convene a special general meeting "to consider the position of the profession in reference to the establishment of provident dispensaries in Birmingham". That meeting was held on Thursday last, January 31st; and we doubt not that such resolutions were passed as will lead to such conjoint action between members of the Branch and the Provident Dispensary Committee, as will result in a complete rectification of the scheme in accordance with "the legitimate requirements and views of members of the medical profession".

##### CHEAP CONSULTATIONS.

A PAMPHLET which Mr. W. H. Alger has recently published, with regard to the amalgamation of the free and provident dispensaries at Plymouth, contains the following statement.

"A striking illustration of the unwise prodigality of the medical profession is to be found in the Plymouth Public Dispensary. At this institution, four physicians and four surgeons gave, during the past year, their best advice to nearly four thousand (3,928) patients. Each of these persons might have had advice and medicine for six weeks; and, supposing that ten interviews took place between each ticket-holder and his medical attendant during the six weeks, either at the patient's house or at the Dispensary (and I understand from one of the staff that this number is below the real average), this will represent about forty thousand (39,280) interviews or visits. Now, what is the sum paid for this enormous amount of mental and physical wear and tear? Six of these gentlemen get absolutely nothing, whilst the other two, who do most of the home visiting, receive £120 *per annum* between them; and, dividing this sum by the figures just quoted, it will be found that the medical profession was paid at the preposterous rate of less than three farthings for each consultation or actual home visit."

##### THE BATTERSEA PROVIDENT DISPENSARY.

IN submitting their report for 1877, the committee state that the results of the year's work are very encouraging. The number of benefit members shows a marked increase, and the balance divisible among the medical officers is greater than last year. As our readers are aware, this dispensary was converted from the free to the provident system in 1875. This report, therefore, includes only the second year of its existence as a provident institution. During the first year of the dispensary

in its reorganised form, 3,634 benefit members entered their names, of whom apparently about 2,150 continued to subscribe. During the year just ended, 4,006 persons have been entered, and apparently about 2,460 are permanent members. The proportion of the receipts finally payable to the medical officers was £112 9s. 4d. in 1876. It would have amounted to £143 os. 5d. if there had not been a necessity to use part of the subscriptions in completing the fitting up of the dispensary. For the past year the amount divisible is £242 8s. 10d. The payments by members in 1876 amounted to £312 16s.; consequently the proportion of this sum payable to the medical officers would have been 45.7 per cent., if no part of the subscriptions had been spent in fittings. This year the receipts from members have been £399 11s. 6d., and of this £242 8s. 10d., or about 60 per cent. is payable to the medical officers. With the increase of numbers has come greater economy, because the arrangements of the dispensary were made with a view to an extended list of members. The committee say they "cannot close their report without expressing their strong feeling of the value of the services given by the medical officers. In one sense those services may be properly spoken of as 'given'; but, if so, they are given in the best possible way, so as not to cramp or limit the entire freedom of the benefit members. It may be truly said that a gift judiciously made is often doubled in value to the receiver; and this expression may be appropriately applied to the care and attention of those officers whose services the committee desire to acknowledge."

#### A YEAR'S WORKING OF A PROVIDENT DISPENSARY.

AT the meeting of the Committee of the Royal Victoria Dispensary at Northampton, held on January 25th, Mr. Becke, the honorary secretary, reported that the net amount due to the three medical officers for their year's services was upwards of one thousand eight hundred pounds, after payment of drugs and all other expenses. The sum payable to the senior medical officer was nearly one thousand pounds. Mr. Becke believed this is the largest sum ever paid by any provident or charitable institution to a medical officer for a year's services.

## ASSOCIATION INTELLIGENCE.

### SHROPSHIRE AND MID-WALES BRANCH.

A QUARTERLY meeting will be held at the Salop Infirmary on Tuesday, February 12th, at 6.30 P.M.; J. RIDER, Esq., President, in the Chair.

The Secretary will feel obliged to those members who intend to read papers if they will signify the same to him before the day of meeting.

HENRY NELSON EDWARDS, *Honorary Secretary*.

Shrewsbury, January 30th, 1878.

### LANCASHIRE AND CHESHIRE BRANCH.

THE first intermediate meeting of this Branch will be held at the Town Hall, Oldham, on Tuesday, March 5th, at 3.30 P.M.

Dr. W. H. Broadbent (London) has kindly consented to read a paper on the Mechanism of Speech and Thought as illustrated by Pathology.

Members wishing to read papers or to exhibit specimens are requested to communicate with the Honorary Secretary as soon as possible.

Dinner will be provided at 6 o'clock.

D. J. LEECH, M.D., *Honorary Secretary*.

96, Mosley Street, Manchester, January 31st, 1878.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE fourth ordinary meeting of the session 1877-8 was held in the Queen's College on January 10th, 1878: present, SAMPSON GAMGEE, Esq., President, in the Chair, and thirty-six members and visitors.

*New Members.*—The following gentlemen were elected members of the Branch: Dr. Chown and Dr. J. Wood, Birmingham; Mr. G. Holloway, Cannock; Mr. H. B. Walker, Kidderminster.

*Communications.*—1. Mr. Sampson Gamgee showed a modification of Sayre's Apparatus which had been constructed, on his suggestion, by Messrs. Salt and Son.

2. Dr. A. H. Carter read a paper on a New Method for the Quantitative Estimation of Urea in Urine.

3. Dr. Balthazar Foster read a paper on Sudden Death in Diabetes Mellitus.

## CORRESPONDENCE.

### PHYSICIANS' FEES.

SIR,—You have opened your columns to what, I fear, you may find a rather overwhelming flood of correspondence on the above subject. It does seem strange that some physicians should only now commence to complain of the injustice dealt to them by an indiscriminating public, to whose sense of honour it has been their pride and privilege to entrust the amount of honorarium expected by them for services rendered. While Fellows of the College of Physicians are bound down by the restrictions as to recovery of fees at present imposed on them, there is no help out of it, as far I can see, and the dishonest portion of the public will always be ready to take advantage of these circumstances whenever it is possible to do so.

I cannot but think that, if there were proper accord between those practising as pure consultant physicians and those gentlemen who practise in a less restricted manner, some mode of distinguishing the "black sheep" would be soon found out, at least as far as regards provincial towns of sufficient importance to give scope for consultation practice. "Consulting physicians" are occasionally apt to draw a broad line of distinction, socially and professionally, between themselves and others who may choose to practise in a different way, but who are as well born, as well educated, and as well qualified as themselves; men who will not brook professional dictation or social snubbing; the ranks of our profession are rapidly being filled with such men, totally different from the general practitioner of past days. If consulting physicians were more anxious to greet such men rather as their equals than as their inferiors, and to cultivate the goodwill of the profession in preference to the *vox populi*, I have little doubt that professional combination would be found sufficient protection against public dishonesty.

Beyond all doubt, the improvement in professional education during the last quarter of a century, and the generalisation of knowledge thereby, have considerably diminished the numerical amount of consultations, excepting in certain specialties; the greater, therefore, is the necessity for the consulting physician of the present day to be a man *sans reproche*, as regards professional conduct.

Diminution of consulting business has possibly forced some and tempted many to try to make up the deficiency by family practice, on terms which place them in direct competition with those gentlemen whom they should expect to call them in as consultants. Surely, such men cannot expect to have the pull both ways; they must choose between the profession and the public, or they will undoubtedly fall "between two stools." If a humble representative of the "working bees in the professional hive" might venture to advise the *Dii majores* yet consulting physicians, I as such would advise them as follows. 1. By social and professional conduct, make yourself worthy of the eminent position which you would hope to retain, and which, by pursuing an undeviating course of professional integrity, you will assuredly retain through the good will of your professional brethren. 2. Fix such a price on your opinion, if founded on attested scientific and practical knowledge and enhanced by the corroborative opinion of your professional brethren, as will place you above suspicion of competing with those whose lot may be cast in rougher, though not less worthy, lines: gentlemen who, in their professional intercourse with you, will take care that no pecuniary disadvantage accrues to their esteemed friend the "real consultant physician."—I remain, sir, yours faithfully,

January 26th, 1878.

P.S.—I trust that the term of "general practitioner" will soon be completely exchanged. In its original meaning, the term is dishonest, professionally obsolete, and I am fully convinced that, in a social point of view, with the public it is not a term likely to elevate professional status.

SIR,—I am sure each of your correspondents who writes on this subject has in view the honour and wellbeing of our profession. If, in this spirit, the subject can receive a complete reconsideration, with a view to improved arrangements, in accordance with present conditions and the altered value of money, I think the time for doing so has fully come. But the whole subject should be taken together. House-rent, wages, hire, the cost of living, etc., have all become much more expensive; the members of many occupations combine to keep up their charges; the medical profession is one of the few which does not do so, its members too often outbidding one another in offering their services to the public. And the public has come to think it granting a favour to the medical man to allow him to inspect disease

to suggest a remedy. We must all have noticed this again and again. Our services are made much too common, partly by the injudicious or self-interested action of some of us, partly by the circumstances under which we work, among which the most notable point is the custom of giving our services gratuitously. This, which ought to be the exception, only done in special cases, has come to be the rule and the system. There ought now to be an end to it. The public ought now to be made aware that medical men are no more to be called in to work for nothing than solicitors, barristers, clergymen, or those of any other profession. Each of us, in his own place, remembering that he represents the profession in that place, should so manage as to let this be understood; it may be discreetly done, and each would find himself a gainer while helping all. And fees, whether physicians' or any other, should always be regarded as due at the time, and should be obtained at the time, whenever practicable. By doing this, each practitioner will gain considerably, and will often retain for himself patients who, if allowed to run up an account, will leave both account and doctor or go elsewhere. I speak from actual and long experience. It is a very common notion that medical men need not be paid at the time, but that anyone may come and consult them without present payment, and that an account is to be sent in some time or other. This should never be permitted. Strangers and chance patients should always pay at once. Those following fee-practice should not allow the rule of their practice to be infringed. Those who must send accounts should view the doing so as an exception, only granted to known and settled residents: the rule of cash payment being applied to all others. Accounts should be punctually sent in, and at intervals as short as possible, either as soon as attendance ceases, or monthly, quarterly, or half-yearly, but certainly never less than annually. Those who never send in their accounts do great injury both to themselves and the profession. I know of one who, with a limited practice, has owing to him about £1,000, simply because he never sends in his bills. Such conduct fosters the prevalent notion that it is not very necessary to pay a medical man. There seems a good deal, both in the profession and out of it, that wants to be set to rights. Such things as visits near home, charged *nil*; consultations with another practitioner, *nil*; vaccination, *nil*; night-visits, half-a-crown; powders, sixpence; diets, half-a-crown a head, with ten shilling and fifteen shilling midwifery, need immediate revision. The leaders of the profession, too, ought to charge higher fees. But nothing hurts the profession more than unfair charges made to a patient, or the least approach to dishonesty therein, or even the appearance of it. Medical men ought to be trusted; that is their rightful and due position. But any doctor who so acts as to make him not to be trusted inflicts on the whole profession a grievous injury, and ought to be turned out of it. In every possible case, payment for service rendered should be sought as a fee at the time. In certain cases, for instance, always in venereal cases, and with strangers and lodgers, this should be insisted on. I quite agree in the suggestion that "some fair and reasonable scale of fees should be arranged immediately, either by the General Medical Council or by the British Medical Association; and that steps be forthwith taken for their universal adoption by the profession".

I formerly addressed to you a letter on the subject of fees, and am glad to see the subject at length taken up.—Your obedient servant,  
January 28th, 1878. A COUNTRY SURGEON.

### THE CORONER'S COURT.

SIR.—Your readers should feel obliged to Dr. A. S. Taylor for his kindness in giving them, in his most exhaustive memorandum on the appointment of coroners, the benefit of his great experience on the subject.

It is satisfactory to see that Dr. Taylor insists on the importance of the examination-test of competency, and I hope he will see the advisability of refusing to give to county or borough magistrates the power of selecting the coroner. Scientific gentlemen should not be subjected to the expensive and humiliating ordeal of canvassing the magistracy or any other body of men. I venture to think that the army and navy medical examinations, with the interim of study, would form good models on which to base the examination of students and applicants for the coronership. I would have the candidates to pass at the outset a competitive examination to determine the eligibility of each, after which the successful candidates should be referred to appropriate legal and medical courses of study, which might be pursued at the Temple and London medical schools, and then, after a certain time, these candidates should undergo a pass examination, when each man's marks should be carefully noted, and the value and priority of the appointments given according to merit.

In reference to the present coroners, it is proposed, in paragraph 17, to retain them in full possession of their offices and emoluments. I do not think it would give public satisfaction to retain men in office whose inefficiency has given rise to so much dissatisfaction. Of course, there are several clever and estimable men among them, but, as a class, they have been weighed in the balance of public opinion and found wanting. I would beg to suggest, then, that in order that the proposed new state of things should come quickly into operation after the passing of the Bill, provision should be made that the present coroners should resign their posts after a stated time. If they be retained in office, posterity, of course, will be the chief gainer by the reform.

The memorandum refers, in paragraph 26, to medical coroners holding inquests on their own patients. A system which permits a coroner to hold inquests on his own patients is indefensible, and is, I believe, as injurious to the majority of the medical profession as it is viewed with disfavour and suspicion by the public at large. A little time ago, I read in a newspaper of a coroner, when holding an inquest on a patient of his own who died suddenly under peculiar circumstances, making it the occasion for delivering to the jury some laudatory remarks on his own and his partner's high professional abilities; but this same coroner, when holding an inquest on a woman who had been attended by a neighbouring brother general practitioner, was so severe in his remarks towards him, that a leading medical journal took the coroner to task for it. Medical men and solicitors in practice should not be allowed to hold the coronership; for, with the best intentions, they can hardly act independently, for fear of giving offence to their patients and clients, by whom they have for the most part to live.—I remain, sir, your obedient servant, WILLIAM O'NEILL, M.D., M.R.C.P.  
Lincoln, January 26th, 1878.

### THE ORGANISATION OF CHARITY IN HOSPITALS.

SIR.—As I trust the valuable letters of your correspondent, "A Member of the Charity Organisation Society", will be republished in a form in which they will be readily accessible to the subscribers to our hospitals and the public generally, I hope you will allow me to indicate a few points touched on in the letter published in the JOURNAL for January 5th, on which it seems to me a little additional information might be given. And, first, as to St. Bartholomew's Hospital, which is classed among those that have resisted every appeal, and have refused to make the smallest attempt at reformation: I have recently been informed, on the highest authority, that an endeavour is being made by the treasurer, Sir Sydney Waterlow, to diminish what we reformers consider to be the evils of the casualty out-patient system at that institution, by strictly cautioning each student who is admitted to the post of dresser not on any account to treat any patient on his own responsibility, and to regard himself merely as the mechanical agent of the qualified medical man who is present; also that there is a lay officer of the hospital constantly present in the casualty-rooms to see that these directions are carried out, and, if necessary, to prevent the charity from being used (or rather abused) by those well able to pay. As it was for bringing forward some cases treated by students before these regulations were thought of that I was subjected to some annoyance, a few years ago, I may be permitted to congratulate the profession on this tacit admission on the part of the hospital authorities that some change was needed in the former system, and to suggest to your correspondent that, after all, St. Bartholomew's is not quite so impenetrable to reasonable appeals as might be inferred from his letter.

Next, as to the London Hospital, I hardly think your correspondent has done justice to the very full discussion of the subject of out-patient reform which took place there in 1873-74. A committee of eighteen gentlemen, including among its members such well-known names as Sir T. Fowell Buxton, Mr. (now Sir Edmund) Currie, Mr. Baring, M.P., Dr. Herbert Davies, Dr. Andrew Clark, and Mr. Jonathan Hutchinson, presented, in July 1874, as the result of their discussions, a very elaborate report, in which, after denying the existence at their hospital of any such evils as overcrowding of out-patient-rooms, deficient medical attendance, or improper issue of medicines or prescriptions by unqualified persons, they addressed themselves to the question whether there was any abuse by persons obtaining medicine and advice gratuitously who could afford to pay, and this evil they were obliged to admit did exist, but, in their opinion, to but a limited extent. The mode in which the committee set themselves to prove the "strictly limited" extent of this abuse was as follows. Taking the hospital statistics as they had hitherto been published, it appeared that between sixty thousand and seventy thousand out-patients were reported to be treated every year. From these, the committee subtracted twenty-five thousand patients who received a supply of medicine only, but appa-

rently got no medical advice whatever. The remainder, whom they considered the genuine out-patients, they divided into three classes: 1. Twenty-four thousand, consisting of accidents, minor casualties, etc., which "hardly come within the scope of this inquiry"; 2. About three thousand renewals; 3. Only sixteen thousand and ninety-four about whom the committee was doubtful whether they were entitled to gratuitous relief or not! This report is in every way a remarkable one, and your correspondent will find it quoted in a paper in *Fraser's Magazine* for November 1874, should the original not be available. It concludes by recommending the trial for a year of what the committee termed "a compromise between the out-patient system as now organised and that total abolition, both of the department and of governors' letters, which to some appears desirable": very remarkable words truly from a committee such as this, and worthy of being pondered over at the present time, when the hospital is notoriously in difficulties for want of funds.

Then, again, as to the Great Northern Hospital; previously to the closing of the out-patient department at that hospital, the number of out-patients treated was said to be over sixty thousand. Since then, it has been as low as twelve thousand in 1874 and twenty-three thousand in 1876, according to the *Medical Directory* of the following years. Has anybody at the hospital ever heard of any injury to the poor of the neighbourhood in consequence? Has a single necessitous person been obliged to do without medical assistance in consequence of the temporary closing of the out-patient department there? The answers to these questions ought to be readily obtainable from the officials or medical staff, and they would, I venture to think, if added as an appendix, render your correspondent's letters still more valuable.—Your obedient servant,

H. NELSON HARDY.

London, January 1878.

#### ADMISSION OF LADIES TO THE MEETINGS OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—I have to ask that you will kindly insert the following letter addressed by me to the Secretary of the British Medical Association, together with the resolution forwarded to me, in reply, from the Committee of Council of the Association.

"December 21st, 1877.

"My dear Sir,—After some consideration, I have resolved to ask you to bring the following question before the Council of the British Medical Association, and to favour me with a reply. The question which I desire to put is this: Are women to be permitted in the future to attend the meetings of the Medical, Surgical, and other Sections of the Association, and to take part in the discussions at such meetings? I had believed that this question was answered in the negative by a large majority of the Association a few years ago. At the last meeting held at Manchester, a lady was present, and spoke in a discussion in the Section of Medicine.

"As I do not intend to be a member of any society where medical topics are debated in public between men and women, I shall be glad to learn the decision of the Council in this matter, reserving to myself the right to publish this inquiry, and the reply which I may receive."

"To Francis Fowke, Esq.

(Signed) WILSON FOX."

In reply, I have received from Mr. Fowke the following resolution:

"That Dr. Wilson Fox be informed that the Committee of Council have no power to prevent ladies who are members of the Association from attending the meetings of the Association."

I have to add that, on the receipt of this resolution, I have written to the Secretary of the Association, stating that the decision of the Committee of Council has left me no option but to request that my name be removed from the list of the members of the Association. The matter is one for individual opinion; but I think it right to call the attention of the members of the Association to a question which appears to me of considerable importance; viz., how far public discussions on medical topics at which men and women are present, and on which no restrictions are placed, are consistent with the rules of propriety and delicacy which have hitherto been generally held to obtain in the relations between the sexes.—I remain, sir, yours faithfully,

London, January 1878.

WILSON FOX.

A CENTENARIAN.—A man named Anton Miktancic is reported to have died lately in Trieste, being within three months of completing his 114th year.

DONATIONS.—The Building Fund of the Belfast Hospital for Sick Children has received £30 from Mr. Carlisle and £25 from Mr. Richardson. The Right Hon. W. Tighe has given £100 to the Convalescent Home, Stillorgan.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### ANALYSTS' REPORTS.

MR. E. W. T. JONES, public analyst for the county of Stafford, in his report for the quarter ending Michaelmas last, states that he examined two hundred and seven samples, of which thirty-two, or 15.45 per cent. were adulterated. These included four samples of coffee adulterated with chicory; thirteen of gin, varying from 37 deg. to 54.4 deg. under proof; one of milk, adulterated with 19 per cent. of added water; two samples of mustard contained wheat flour; six samples of oatmeal contained sharps and barley-meal; one sample of whisky was 47.4 deg. under proof, and five samples of pills were not what they were sold as.

Mr. A. J. M. Edger, public analyst for the county of Durham, reports that, during the quarter ending Michaelmas last, he analysed two hundred and eight samples, seventy-four of them being adulterated—viz., fifty samples of various spirits, two of oatmeal, eight of pepper, five of soda-water, one of mustard, one of cider, and seven of milk.

### ACTION AGAINST A MEDICAL OFFICER OF HEALTH.

AN action of some importance to medical officers of health has lately been tried in the Auckland County Court. It was brought by a fisherman against Mr. Manson, the medical officer of health, and also against the Inspector of nuisances, for illegally seizing fish (herrings) as sound and fit for food which were alleged by the plaintiff to be perfectly wholesome and good. The plaintiff had been summoned before the local magistrates for offering the fish for sale, but the case was dismissed. The plaintiff gave evidence to the effect that the fish were good, their gills being red; and also that they were bright and fresh. This statement was supported by several witnesses, who testified to having eaten some of the herrings on the same night the seizure was made. The assistant-inspector to the rural-sanitary authority, the market-keeper, and Mr. Jobson, who ordered their destruction next day, as well as the medical officer of health, gave evidence as to their unsoundness. The judge gave a verdict for the defendants, with the expenses of one witness only. At the next meeting of the local authority, Mr. Manson made application for the expenses he had incurred and remuneration for the time he had lost in attending at the police and county courts. Only one guinea, however, was voted, because the case was lost at the police-court; which, considering he lost three days in attendance, is but a poor *solatium*. The case is, however, of greater importance than the mere question of loss of expenses, as it is not generally known that an action will lie against a medical or other officer who shall seize any article as unfit for food while it is in a wholesome state. Actions have been commenced against more than one metropolitan medical officer of health, not only for the value of the articles seized, but for injury done to the business of the owner thereof; but they were either settled in some way or abandoned, as they never came to trial. Under these circumstances, it may be somewhat dangerous to seize carcasses of animals which have been killed when suffering from lung disease, unless the flesh be changed in colour and consistency. Every officer must, therefore, be prepared to carry out his duties at his own risk, in the same way as he carries on his private practice subject to actions for malpractice. The defendants were represented by Mr. Proud; but whether or not he was the clerk to the local authority is not stated; and we do not, therefore, know whether or not Mr. Manson was properly supported by his board.

### PREVENTION OF SMALL-POX IN LEICESTER.

DR. JOHNSON, the medical officer of health, successfully adopted the plan of removing all the inhabitants of the poorer houses in which a case of small-pox occurred to a quarantine establishment in the hospital, and retaining them there for at least fourteen days. He removed in all twenty-two persons, who were apparently in good health at the time; and three of these sickened at the following periods after their removal; viz., one in forty-eight hours, another in seventy-two hours, and the third on the twelfth day; so that all these must have been infected before removal. The disease had appeared in six places before these families were removed; but not one case had occurred at the date of the report, viz., fourteen days after the occurrence of the case last taken in at the hospital. Dr. Johnson seems to think that

his plan is novel; but in this he is in error, as it has been practised in the metropolis and elsewhere, not only for this disease, but also for cholera. It is undoubtedly very useful at the commencement of what might otherwise have been an epidemic, and is worthy of being more extensively carried out, especially as Dr. Johnson says he had no difficulty in inducing the families to remove to the quarantine establishment. He does not say whether or not the fathers of the families, if any, accompanied them; because, in the cholera epidemic, considerable opposition was invariably made, except when the fathers were out of employment; and then at least equal difficulty was experienced, at any rate in some places, in inducing them to leave the comfortable quarters provided for all. This point is not mentioned by Dr. Johnson, and is one which must be taken into consideration if the plan should be largely practised. He does not state also how the "home" was kept together whilst the families were in quarantine.

#### INTERMITTENT WATER SERVICES.

WE have often pointed out the dangers associated with intermittent water services, and we have specially noted the outbreaks of enteric fever, which have occurred in various towns, such as Lewes and Cambridge, where, with an intermittent system, water-closets have been supplied direct from the mains; and, with a view of obviating these dangers, we have strongly urged that all services should be constant, and that the supply to a water-closet should invariably be broken, as by the intervention of a supply cistern. We have also incidentally referred to the probable saving of water, which would be effected by the adoption of these measures; but actual facts on this point have hitherto not been forthcoming. We therefore note with gratification the results which have been obtained in Rugby in this respect. During the course of last year, Dr. George Wilson, in urging upon the Town Council of Warwick the necessity for dealing with their intermittent water supply, and with the branches to water-closets, which were so arranged as to admit of suction of sewer air into the mains, gave the result of his experience of the adoption of similar measures at Rugby. The number of water-closets which were there found to be directly connected with the mains amounted to about two hundred and fifty; and, since they had been disconnected, there had been a saving of waste in water equal to nearly ten gallons per head of the population per day. After some of the closets had already been disconnected, the water supply of the town was, by way of experiment, made constant for a term of three months, and a careful record was kept of the amount daily pumped. From this record it appeared that the average daily quantity supplied during that period amounted to thirty gallons per head. Subsequently all the remaining closets were disconnected, and it was ascertained that, as the result of a month's pumping in the constant service system, the quantity had been reduced to 21.3 gallons per day. In short, so much waste had been prevented that the water supply, which formerly was intermittent, has now been made constant; and that without any increase in the amount delivered.

#### POOR-LAW MEDICAL APPOINTMENTS.

DREW, Clifford Luxmore, M.B., appointed Medical Officer and Public Vaccinator for the Dunchurch District of the Rugby Union.

### MEDICO-PARLIAMENTARY.

#### HOUSE OF COMMONS.—Monday, January 28th, 1878.

*The Medical Profession.*—In answer to Mr. Mills, Viscount SANDON said he was not at present able to inform his honourable friend whether the Government was prepared to bring in a Bill for providing a uniform test of admission to the medical profession in England, Scotland, and Ireland.

*Small-pox in the Isle of Man.*—Sir J. LAWRENCE asked the Secretary of State for the Home Department whether information had reached him of an outbreak of small-pox in the Isle of Man; if it be true that the Vaccination Laws are not in force in the Isle of Man; and if any steps have been, or are about to be, taken to remedy this defect.—Mr. KITCHIE asked whether there was the slightest foundation for the rumour that the Governor of the Isle of Man and his family had left the island on account of the prevalent character of the disease.—Mr. CROSS was quite sure that anybody who knew the character of the Governor would not think for a moment that he was capable of deserting his post at a time of danger. It was utterly untrue that he had left the island. With regard to the outbreak of small-pox, it was quite true there had been a violent outbreak of that disease. The disease was spread owing to the Vaccination Law not being in force in the island. But a Bill

had now passed through the local legislature, and it would have received the Royal Assent at the present but for a small technicality which he hoped to correct. Papers connected with the question of vaccination in the Isle of Man would soon be laid before Parliament.

*Tuesday, January 29th.*

*Small-pox in the Isle of Man.*—In answer to a question from Mr. Adam, Mr. CROSS said I am happy to inform the House that the Isle of Man is now practically free from small-pox, the disease being limited to two or three convalescent cases.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentleman passed his examination in the science and practice of medicine, and received certificate to practise, on Thursday, January 24th, 1878.

Clark, James Richard Andrew, 16, Cavendish Square, W.

The following gentleman also on the same day passed his primary professional examination.

Midwinter, Edward James Henry, London Hospital

#### MEDICAL VACANCIES.

THE following vacancies are announced:—

**BRECON INFIRMARY**—Resident House-Surgeon. Salary, £100 per annum, with apartments, attendance, fire, and lights. Applications to be made on or before the 11th instant.

**CHORLTON UNION**—Workhouse Medical Officer. Salary, £250 per annum, with firing, light, attendance, and furnished apartments. Applications to be made on or before the 5th instant.

**CLIFTON UNION**—Medical Officer for the District comprising the Islands of Inishboffin and Shark. Salary, £90 per annum, exclusive of Registration and Vaccination Fees. Applications to the 13th instant.

**DENTAL HOSPITAL OF LONDON**—Dental Surgeon. Applications to be made on or before the 13th instant.

**GENERAL INFIRMARY, Northampton**—Surgeon. Applications to be made on or before the 27th instant.

**IPSWICH BOROUGH LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance.

**KENT COUNTY LUNATIC ASYLUM**—Assistant Medical Officer and Dispenser. Salary, £165 per annum, with furnished apartments, milk, vegetables, washing, and attendance. Applications to be made on or before the 6th instant.

**LIVERPOOL ROYAL SOUTHERN HOSPITAL**—Two Honorary Surgeons. Election in February. For particulars, apply to Honorary Treasurer.

**LONDON HOSPITAL**—Assistant-Physician. Applications to be made on or before the 4th instant.

**METROPOLITAN FREE HOSPITAL**—Assistant Physician. Applications to be made on or before the 12th instant.

**NORTHAMPTON GENERAL INFIRMARY**—Physician. Applications to be made on or before the 20th instant.

**QUEEN'S UNIVERSITY IN IRELAND**—Examiners for 1878 in the following subjects, at the salaries stated. Medicine, £100; Surgery, £100; Midwifery, £75; Materia Medica, £75; Medical Jurisprudence, £75. Applications to be addressed to the Secretary, at Dublin Castle, up to the 15th instant.

**ST. GEORGE'S HOSPITAL**—Surgeon and Assistant-Surgeon. Applications to be made on or before the 13th instant.

**SLIGO UNION**—Medical Officer of Carney Dispensary District No. 1. Salary, £120 per annum as Medical Officer, and £20 yearly as Sanitary Officer, with the usual Registration and Vaccination Fees. Applications to the 4th instant.

**TOBERCURRY UNION**—Medical Officer of Coolaney Dispensary District. Salary, £120 yearly, with Registration and Vaccination Fees. Applications to the 11th instant.

**WEST HERTS INFIRMARY**—House-Surgeon and Dispenser, who shall also be Assistant-Secretary. Salary, £100 per annum, with board, furnished rooms, fire, lights, and attendance. Applications to be made on or before the 7th inst.

#### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

EVANS, C. W., M.R.C.S., appointed a Clinical Assistant at the Royal South London Ophthalmic Hospital.

\*FLETCHER, George, M.D., appointed Medical Officer to the Albert Memorial College, Framlingham, Suffolk.

HOBSON, Lewis John, M.B., appointed Senior House-Surgeon to the Newcastle-on-Tyne Infirmary.

\*HUMPHREYS, Henry, M.D., appointed Senior Physician to the Hospital for Sick Children, Pendlebury.

\*NELL, Channing, M.D., appointed Junior Physician to the Hospital for Sick Children, Pendlebury, *vice* A. Humphreys, M.D., promoted.

#### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

#### MARRIAGE.

JONES—BLACKBURN.—On January 3rd, at Chicago, U.S.A., by the father of the bride, assisted by the Rev. W. C. Young, Percy Owen Jones, M.R.C.S.E., to Alice, eldest daughter of the Rev. W. M. Blackburn, D.D.  
WESTMORELAND—YOUNG.—On January 23rd, at the Cathedral, Manchester, by the Rev. Minor Canon Clement Smith, M.A., assisted by the Rev. Thomas Charles Westmoreland, M.A., Vicar of Shipton Thorpe, \*Joseph Westmoreland, Surgeon, Cheetham, Manchester, to Mary, eldest daughter of the late John Hindle Young, of Crumpsall Old Hall, Manchester.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.—London, 3 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 3 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY ....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2.15 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Medical Society of London, 8.30 P.M. Lettsomian Lecture by Francis Mason, F.R.C.S.; subject, "The Surgery of the Face".

**TUESDAY.**—Pathological Society of London, 8.30 P.M. Dr. Yeo: Heart and Aorta—Sequel to Case of Rupture of Aortic Valve. Mr. T. Bryant: 1. Prostatic Tumours removed in Lithotomy; 2. Impacted Fracture of the Shaft of the Femur. Mr. Nunn: Sequel of a Case of Recurrent Sarcoma. Mr. Morgan: Case of Congenital Obstruction to the Common Bile-duct. Mr. Lennox Browne: 1. Cancer of the Tongue involving the Tonsil (living case); 2. Cancer of the Tonsil; 3. Encephaloid Cancer of the Larynx. Mr. K. Thornton (for Mr. Taylor): Tumours of both Ovaries. Mr. K. Thornton: Cysts from the Peritoneum. Mr. Wood: Cystic Disease of the Thyroid. Dr. Samuel West: Thrombosis of the Vena Cava and Portal Vein. Dr. Legg: 1. Aneurysm of the Right Auricle; 2. Melanotic Liver; and other specimens.

**WEDNESDAY.**—Royal Microscopical Society, 8 P.M. Anniversary Meeting. President's Address, etc.—Obstetrical Society of London, 8 P.M. Dr. MacCallum, "Report of the University Lying-in Hospital, Montreal"; Dr. Greene, "Case of Puerperal Convulsions"; and other communications.

**THURSDAY.**—Harveian Society of London, 8 P.M. Mr. Hornsey Casson, "Gun-shot Injury of Elbow-joint"; Dr. Fitzpatrick, "On the Defective Drainage of West End Houses, and Cases of Zymotic Disease arising therefrom".

**FRIDAY.**—Clinical Society of London, 8.30 P.M. The President, "Specimens of Tendon Ligatures"; Mr. Nunn, "Two Cases of Cancer; Mr. Hutchinson, "Retinitis Hæmorrhagica: its connection with Gout and probable dependance upon Thrombosis of the Vein"; Mr. Balmanno Squire, "Severe Psoriasis treated by daily Immersions"; and a "Case of Psoriasis treated by Chrysophanic Acid" (living specimens).

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

## ANIMAL VACCINE.

**A MEMBER.**—The establishment in Brussels is the Institut Vaccinal de l'Etat, the director of which is M. Evariste Warlomont. Our correspondent will find information on the subject in a letter from Dr. Warlomont, published in the *BRITISH MEDICAL JOURNAL* for January 27th, 1877.

## FILTERS.

**SIR.**—Mr. J. Burrows wishes to know of a filter easily kept clean and in order. In August 1871 I bought one of Spencer's magnetic iron filters. It has been in daily use from the day it was bought to the present time. It has not been cleaned, neither does it appear to require cleaning. The water that comes from it is very clear, very agreeable, and is largely consumed by my family and myself. The theory of its dirt-consuming power may be read in the prospectus issued by Mr. Spencer, the inventor of the filter, who resides at 32, Euston Square, where there is, or was, a depot of them. I enclose my card.—Very faithfully yours,  
January 1878.

E. H. R.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**ADVERTISERS** are requested to take notice that the regulations of the *Post-Office* do not allow letters to be addressed to initials and directed to any *Post Office* in the United Kingdom, but letters may be addressed to initials to the *JOURNAL* Office or any stated address other than a *Post Office*.

## SORE NIPPLES.

**DURING** the last month or so of pregnancy, wash the nipples with equal parts of brandy and water morning and evening; and, if there be any cracks, apply a lotion of sulphurous acid, about 1 to 8, on lint. Proved.

A. B. MUNER, M.D., C.M.

157, Otley Road, Bradford, Yorkshire, January 26th, 1878.

**SIR.**—If E. R. S.'s patient will bathe her nipples twice or thrice daily from this time till her confinement with a lotion of tincture of arnica and water (1 to 7), and take care that there be no pressure from corsets or dress, she will, I believe, be free from sore nipples afterwards. During lactation, a lotion of brandy and water (1 to 2) may be applied to the nipples between the infant's feeding hours, if they are inclined to be tender, taking care to bathe them with warm water immediately before the child is put to the breast.—I am, sir, your obedient servant,  
Chester, January 28th, 1878.

C. S. WILES.

**SIR.**—I notice that one of your correspondents has some difficulty with the treatment of the nipples. As I had the same experience, I was led to examine the whole subject, and the results of my investigation are published in the *Obstetrical Journal* for the present month. If E. R. S. have not access to that journal, I shall be glad to send him a reprint of my paper should he communicate his address to me.—I am, yours very truly,  
4, Newton Terrace, Glasgow, January 29th, 1878.

SAMUEL SLAUN.

## VILLOUS DISEASE OF THE BLADDER.

**SIR.**—In the *JOURNAL* of January 19th, there is a letter from "L.R.C.P.Lond.", in which he states that my case of "villous disease of the bladder" is open to doubt, and questions the propriety of the treatment. These are, however, matters of opinion. It was not to discuss the diagnosis or treatment that I reported the case, but to show how slight an injury to the urethra could give rise to alarming symptoms. I wish to inform L.R.C.P. that we did not, at our consultation, come to any decided diagnosis; but we agreed that the hæmorrhage came from one of two sources—*i.e.*, the prostate gland, or from a villous growth involving the neck of the bladder. In trying in a catheter, we hoped to check the bleeding, if coming from the former; whilst it would prevent the severe and painful straining which caused so much distress. This it did, to the great relief of the patient. L.R.C.P. could not have read the case, or he would have seen that the patient injured his own urethra through getting out of bed some hours after my visit. The patient is now tolerably comfortable, but occasionally passes a little blood with his urine. He has also pain at the neck of the bladder, with frequent micturition; but there has been no retention.—I am, sir, yours, etc.

WM. STAMFORD, L.R.C.P.Lond.

**SIR.**—To Mr. Stamford's communication on a "case of villous disease of the bladder" in the *JOURNAL* of January 5th, he makes this statement, "The feature of interest, however, in the case is the occurrence of the rigor following a misplacement of the catheter, which he had worn without hindrance for four days. To what may that rigor be referred? That it was not the precursor of any *pyrexia* symptoms, puts the view, I think, of its being due to septicæmia from the seat of disease out of the question". But are not a temperature of 103 deg., and a skin which was "very dry", with a defervescence accompanied by a skin "acting profusely", febrile symptoms? And are not the words I have italicised in the above quotation somewhat inconsistent with Mr. Stamford's subsequent expression, "the remarkable severity of the transient pyrexial state". In the *JOURNAL* of January 26th, 1877, he will find a detailed account of what, I think, was an undoubted case of short-lived septicæmia after the prolonged use of an urethral bougie, which lasted thirty-nine hours, counting from the rigor, until the normal temperature was restored. I am disposed to think his case was similar both in cause and nature to my own, but more transient, as we may conclude that it lasted about ten or twelve hours. There is a great similarity between the two cases, but there is one striking difference: in his case there was profuse perspiration, and in mine there was absolutely none, but it terminated with continuous vomiting and a herpetic eruption: the cases thus showing a remarkable contrast in the route (apparently) taken by the poison for its elimination.—I am, sir, your obedient servant,  
Ennisorthy, January 26th, 1878.

THOMAS DRAPE, M.B.

**SURGEON-MAJOR FERGUSON** (Camp Hagar).—We have made further inquiry on the subject of our correspondent's letter, and we are informed by Mr. Pillscher that the calculation of the magnifying powers of the objectives of his international microscope was made independently in every case by an accomplished expert. Five hundred of them are, we believe, in use in the London medical schools and in the medical colleges of Bombay and Calcutta; and these instruments, of which we have had occasion to speak favourably in the first instance, have not in any case been the subject of any complaint. We have reason to believe that the powers are some fractions under rather than over the figures stated, and we believe that, if our correspondent again tests his objectives, he will find the calculations to be correct.

## TREATMENT OF SCURVY BY THE BINOXALATE OF POTASSIUM.

**SIR.**—Permit me to make a few remarks with reference to your able arguments on the above subject in last week's number of the *JOURNAL*. It is stated, in the information furnished to me by Mr. J. W. Taylor, that out of forty men suffering from scurvy in its most severe form, and treated solely by the binoxalate of potassium, only one died, and he after exposure for seventy hours in an open boat. I venture to submit that this great percentage of cures warrants a more extended trial of the remedy, whether it be an *alkali* or not. If it will be used as a substitute for lime juice it would be invaluable to Arctic sledging parties, where weight and space are a great consideration—two ounces and a half of binoxalate of potassium being about equal, as an ant-scorbutic, to one gallon of lime juice; and if small doses be given, is neither poisonous nor injurious. Your obedient servant,  
Anerley, January 28th, 1878.

W. H. TAYLER, M.D.

## HOW TO FEALEM A BODY.

**SIR.**—Would any of your readers answer this question, or advise as to the best source of information? and oblige,  
ARMENIA.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### EXTIRPATION OF THE LARYNX.

SIR,—In the highly interesting case which Dr. Foulis exhibited at the Medical Society of London on Monday last, there are a few points, which, I think, if he will kindly mention them, may be of advantage in future operations. 1. Barometrical and thermometrical observations; 2. Whether the operating room was artificially heated with dry or moist atmosphere, and its temperature; 3. Previous preparation of the patient; 4. The anæsthetic used, and description of apparatus; 5. Whether any vomiting during or after operation; 6. The condition of the pulse before and after operation and body temperature. I trust, however, Dr. Foulis will not take it amiss by my making these suggestions, or in any way disparaging to his most carefully worked out paper. Might not anæsthesia be administered in the following manner: A ten ounce circular bottle, with a small brass stopcock, situated about half way in its body, to which Dr. Richardson's hand-bellows could be attached, and an exit stopcock at the top of the bottle, to which a piece of India-rubber tubing could be attached, and this could be fitted into the leaden trachea-tube by means of a piece of brass tubing accurately fitting it? Now, if the bottle be one-fourth filled with chloroform (or if this be used, a modification of Clover's apparatus might be used), and the hand-bellows worked, a current of air would be driven into the bottle, and so charged with chloroform or vapour, and carried into the trachea.—I am, yours truly,  
GEN. CHAS. COLES.

#### PROFESSIONAL OBLIGATION.

SIR,—May I ask for a reply to your next issue to the following? Does professional etiquette require that I should give medicine and attendance gratis in the following case? A Mr. T., a M.R.C.S., settled down here a few years ago and kept a *bona fide* chemist's shop, his health preventing him from entering upon regular practice. He had on his bill-heads, "Surgeon and Chemist." His name is in the *Medical Register*, but he made no use whatever of his degree as surgeon in practice. Whatever attendance he required, I always freely gave him, his wife, and family, without charge. He has recently died, after a long illness, and his wife has been confined since with her fifth child. Previously to his last illness, whenever I attended Mr. T. or his family, he dispensed his own medicines, but for the last few weeks of his life I had to do it myself at my surgery. I may add, that before settling down here, Mr. T. went several voyages to India for his health, as surgeon to merchant vessels. I merely wish to be informed whether, according to medical etiquette, I should be expected to give my attendance free in such a case. I enclose my card, and with many apologies for troubling you, remain, yours truly,  
January 29th, 1878.  
A. P. SUFFOLK.

\*. As our correspondent gave his professional attendance freely to Mr. T. during his life, we think that, as a matter of good feeling, and in accordance with what we believe to be the general usage of the medical profession, he should continue to act in the same way towards the widow and family. He must, however, be guided to a great extent by the circumstances in which they have been left.

#### MEDICAL FEES.

SIR,—I am sorry to see from Mr. Brown's letter that he still keeps up the bad practice of charging for medicine and not advice. What is the difference between a druggist and a medical man? I should have answered, one charges for physic, the other for brains. Here, I am thankful to say, the practice is to charge for the visit or consultation, whether or not medicine is given; only charging for medicine when a patient sends for a bottle, etc., of mixture when not being otherwise attended. This, certainly, is a much more dignified position, as the other plan induces the public to think you unduly dose them with physic. I must confess that from Mr. Brown's own letter I think A. B. does much more to keep up the dignity of the profession than he (Mr. Brown) does. When any medical man, whether consultant or otherwise, visits a place at some distance from his residence, it is often customary for him to see others at a less fee than he charges for the ordinary visit; but surely Mr. Brown carries this too far in visiting three or four patients on a round at some distance from home. He may, when first called in, only charge a consultation-fee; but afterwards, if he would have been obliged (if visiting no other patient in that district) to have come specially to see each patient, surely he is entitled to the full fee for each visit. Of course, in country practice, some cannot pay the full fees, and I conclude Mr. Brown would charge the spare more than the village carpenter. Hoping soon to see the advice gratis system a thing of the past, I am, yours truly,  
Exeter, January 26th, 1878.  
F.R.C.S. (by Exam.).

#### DR. DRYSDALE AND THE POPULATION QUESTION.

SIR,—With all due respect to your editorial remarks on the above question in today's JOURNAL, allow me to remark that the views advocated by Dr. Drysdale and by all modern Malthusians have been suggested as remedies for the miseries resulting from the pressure of population on the food supply by the great political economists, of whom the world may well feel proud for their labours in the cause of humanity—viz., J. S. Mill in England, Bettillon and Garnier in France, and Sismondi and Mante-gazza in Italy. Which, I may ask, is the most moral, putting a limitation on the number of a family, or bringing into the world a greater number of helpless beings than can be clothed, fed, and educated? Which is the most degrading giving to the public that knowledge of the population question, in all its aspects, which will cause health, domestic happiness, freedom from care, and the banishment of (landestine sexual abuse, or withholding information, and thus allowing prostitution, venereal disease, poverty, divorce, and death to flourish in our midst? You say "Dr. Drysdale's doctrines are wholly disesteemed by the medical profession." I may refer you to a discussion on the "Happiness of the Community as affected by Large Families," held at the Intellectual Society on July 1st, 1868, Lord Auberley in the chair. The paper was read by James Laurie, Esq., formerly inspector of schools, who advocated the French system of limitation. Several medical gentlemen took part in the debate; among whom, Dr. Roberts supported Mr. Laurie. The Malthusian league has medical men enrolled in it. I may also remark that Professor Bain of Aberdeen agrees in the work which Mrs. Pesant advocates. All new schemes for the amelioration of the sufferings of the people are at first opposed and then adopted: notice the temperance question, vaccination, etc.

I believe Dr. Drysdale has undertaken a noble work, and I may say that the people as a class are as one with him. Surely there is sufficient poverty and evil in the world, without bringing in more to share it than can be provided for.

Trusting I have not intruded too much on your space, I am, etc., yours,

Leeds, January 26th, 1878.

H. A. ALLBUTT, L.R.C.P., etc.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### THE TITLE OF DOCTOR.

SIR,—I hope you will excuse my writing to you on this much vexed question of "Doctor." I am a L.R.C.P. Lond., and do not take the title of Dr., but content myself with physician-surgeon, as the enclosed card will show. I believe the by-laws of the London College of Physicians do not allow its licentiates to take the title of Dr.: why the Edinburgh College should do so I am at a loss to know. Perhaps when we get the conjoint scheme, this anomaly will be done away with.—I remain, yours, etc.,  
C. E. HERON ROGERS, L.R.C.P.L., etc.

Retford, Notts, January 26th, 1878.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Post; The Scotsman; The Cork Constitution; The Freeman's Journal; The Hampshire Post; The Somersetshire Herald; The Isle of Man Times; The Sussex Advertiser; The Herts Advertiser; The Manchester Guardian; The Evesham Journal; The Derbyshire Courier; The Auckland Times and Herald; The Auckland Chronicle; The Western Mercury; The Daily Courier; The Lincoln Gazette; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Devonport Independent; The St. Pancras Gazette; The Bath Herald; The Western Morning News; The Hull News; The Redditch Indicator; The Derby Mercury; The Preston Guardian; The Scarborough Express; The Jewish World; The Durham Chronicle; The Harrogate Herald; The Sunderland Times; The Lincolnshire Chronicle; The Bromsgrove Weekly Messenger; The Manchester Courier; The Broad Arrow; The Cork Examiner; The Cork Daily Herald; The Rotherham and Mashro' Advertiser; The Liverpool Daily Courier; The York Herald; The North Wales Chronicle; The Sheffield Daily Telegraph; The Blyth Weekly News; The Glasgow Herald; The Nottingham Journal; The Eastbourne Standard; The Scarborough Daily Post; The Isle of Wight Observer; The Sussex Daily News; The Metropolitan; The Leeds Mercury; The Belfast News Letter; The Richmond and Ripon Chronicle; The Cambridge Independent; The Madras Mail; The Ashton Reporter; Saunders' News Letter; The Western Mail; The Bath Chronicle; The Bolton Chronicle; The Lincolnshire Chronicle; The Chippenham Chronicle; etc.

\*. We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

# LECTURES ON THE INFECTIVE PROCESSES OF DISEASE.

*Delivered in the Theatre of the University of London.*

By J. BURDON SANDERSON, M.D., LL.D., F.R.S.,  
Professor of Physiology in University College; and Superintendent of the Brown  
Institution.

## LECTURE IV.—*The Germ-Theory, Contagium Vivum, Specific Infections.*

THE task I have set myself for to-day is one of considerable difficulty. I have two pathological theories to discuss, each of which has been the subject of much contention—the theory of contagium vivum and the germ-theory. In many persons' minds, these two theories are so closely associated, that they sometimes seem to be regarded as identical; yet, in reality, they have no necessary connection with each other.

By the expression *contagium vivum*, I mean to designate the doctrine that, when a contagious disease is communicated by the atmosphere, by personal intercourse, or in any other way, that conveyance takes place by specifically endowed organisms, which stand in a similar relation to the disease to that in which the seed does to the plant. For, just as the seed is at once the origin and offspring of the plant, so, according to this view, the morbid germ produces the disease, and is in its turn produced by it. This being understood, it is evident that the term *contagium vivum* relates exclusively to specific diseases, and therefore belongs mostly to medicine.

For a similar reason, the *germ-theory*, which relates to the inflammatory and other consequences of injuries, involves questions which are almost exclusively surgical. That theory teaches that certain organised and living particles of extreme, if not ultra-microscopical minuteness, which are always suspended in the atmosphere, are in such sense the causes of the suppuration and other destructive changes which interfere with the healing of a wound, that (1) if these organisms are excluded, the wound must enter at once on the processes of reparation, and (2) that if these organisms are present, it cannot so heal; and consequently that the whole secret of the successful treatment of wounds consists in the exclusion of that finest form of atmospheric dust which, whatever be the size of its particles, has been identified, as well by physicists\* as by mycologists,† with the contaminating agents in question.

Let me begin by expressing to you, with all due respect, but not the less decidedly, my own personal conviction as to the value of the method of treatment of wounds which is, or professes to be, founded on the germ-theory. It may be said that it is no part of the business of a mere physiologist or pathologist to have any opinion on a practical question. But the present case is entirely an exception. The results are so patent, so conclusive, that it would be as reasonable to doubt of the utility of vaccination as of that of the anti-infective treatment of wounds. The fact that infective action can be prevented in a wound is established with as much certainty as any other pathological fact of which we have gained knowledge by experience. Indeed, if it had been possible to contrive and carry out a series of experiments for the mere purpose of testing it, we could not have had better proofs than have actually been afforded by hospital practice. We are able to compare what is under the improved methods, not only with what *was* before they were introduced, but with what still presents itself, where that "clinical precision," which is the soul of what I may venture to call the new surgery, has not as yet asserted itself.

I have recently been in Germany, and have had the opportunity not only of hearing the opinions of the leading pathologists in that country, but also of seeing some of the practical benefits which the adoption of what they call the "*Listersche Behandlung*" is accomplishing in that country. It is little more than three years since Professor Volkmann of Halle was led to try the antiseptic method. The results of his first experience of it were brought together in the form of a discourse which was delivered before the Surgical Congress at Berlin in 1874. In this dis-

course, he pointed out in the clearest way that the question whether the germ-theory was true or false ought not to have the slightest influence on their minds; that the question was one to be settled merely by experiment—and by experiments of the most agreeable kind—those, namely, in which the subject experimented upon himself derives his principal benefit. Is it the case or is it not the case that, in a wounded surface or an exposed serous surface, the reparative process will, under the influence of the antiseptic treatment, take place without the intervention of suppuration, and to the absolute exclusion of the subsequent destructive and infective processes? This was the question; and the affirmative answer which Volkmann gave, founded on the experience of fifteen months in the hospital of Halle, has been abundantly confirmed since. "In presenting these observations," he says, "I ask myself once more whether, in forming my opinion, I have kept myself uninfected by the prevailing fever" (by which he means what another great pathologist has called the bacterium craze—the tendency to attribute everything to bacterial influence). "I ask myself, and think I can answer, exclusively on the ground of clinical experience." It is quite unnecessary for my purpose, and it would be out of place here, to bring before you the details of Professor Volkmann's results, which can be read in the clinical lecture to which I have referred and in the author's more recent surgical contributions. I may, however, endeavour to communicate to you some impressions which I received in a recent visit to Halle. It is impossible to conceive a more favourable locality for making an experiment of such a nature; first, because the extraordinarily rapid progress of the manufactures of the town has rendered the hospital too small for its requirements, and consequently the proportion of severe cases (as I was able to observe in going round the wards) was very large; and secondly, because the hospital itself is not, perhaps, the worst, but *one* of the worst, that I have ever seen. Situated in the very centre of the town, overshadowed by a huge ecclesiastical building, and having for wards low rooms, each of which communicates with a latrine, and has its beds so close that there is scarcely more than room to pass between them, the hospital presents every circumstance likely to lead to the development of the worst traumatic affections. It is in such wards as these that compound fractures, amputations, and resections have been treated with a success which is up to the best results of London surgery. In a word, the influence of the most unfavourable conditions which can possibly be conceived (the disastrous effects of which were before so overpowering that, to Professor Volkmann, his clinical work had become a burden instead of a joy) have been simply neutralised by the conscientious carrying out, in all its details, with the earnest co-operation of the whole staff of the hospital, of the Edinburgh method.\* Looked at from a pathological, that is from a scientific, point of view, the successful trials which have been made of Lister's treatment during the last few years in the great hospitals of Europe may be regarded as each a several experiment on a very large scale; the whole forming a series of experiments all of which point very distinctly to the same conclusion, that conclusion being, of course, that a serous surface may be exposed, and that living tissues may be incised, or even subjected to serious mechanical injury, without these parts becoming foci of infective inflammation—without any further reaction taking place than is necessary for the constitution of the reparative process. I need not remind you, gentlemen, that our London experience affords us examples (it is quite unnecessary for me to point out where they are to be found) that show that similar skill, care, and accuracy, even when not carried out on the principle of occlusion, lead to similar results; and, further, that in the past, on the whole, our hospital results, as is freely acknowledged by German surgeons, are far better than they have hitherto been on the other side of the Channel. But this consideration does not in the slightest degree detract from the value of German hospital experience for the scientific purposes we have now in view. When, as at Halle, we have pyæmic affections banished from wards which were formerly infested; when, as at Munich, hospital gangrene (a disease which probably a great many of us have never seen), which up to 1854 affected 80 per cent. of the traumatic cases in the hospital, has ceased to exist; when we see the same experience repeated at Strasburg, at Leipsic, at Innsbruck, and I know not at how many other places,—we need no longer wonder that it is common to hear the discovery of Lister spoken of in Germany as the greatest progress in the art of medicine which has taken place in modern times. But it is not, as I said before, with the human life saved and human suffering spared by his improvements that we have to do at present, but with the pathological lesson to be learnt from these results.

\* "The individual particles of the finest floating matter of the air lie probably far beyond the reach of the microscope" (Professor Tyndall, *Philosophical Transactions*, 1876, Part 1, p. 44).

† "Der gefährlichste Staub ist derjenige von dem wir gar keine Wahrnehmung haben." Nägeli, *Die niederen Pilze in ihren Beziehungen zu den Infektionskrankheiten*. Munich, 1877, p. 153.

\* It may be well to note that in Halle, as elsewhere in Germany, rapid improvement is in progress in all matters relating to medical education. Among other things, a magnificent surgical hospital is being built in the most airy part of the town, under Professor Volkmann's immediate direction.

The germ-theory explains everything by saying that the reason why a wound goes wrong is, that atmospheric particles enter in and contaminate it. It compares, in short, the treatment of an operation-wound with one of Professor Tyndall's or M. Pasteur's experiments on spontaneous generation. It professes, indeed, to be an application of the principles and method of such an experiment to a practical purpose. It is perfectly true that the same fastidious precautions which are necessary to command success in the one case are also necessary in the other. What, then, is the difference between them? In the laboratory experiment, the criterion of success is the absence of living organisms. If they appear in the test-liquid employed, the operation is considered as a failure; for, so far as experience has yet taught us, there is no case in which organisms come into existence otherwise than as the progeny or offspring of previously existing bacteria. Are we justified in applying the same test to the antiseptic treatment of an injured surface? From the theoretical point of view, we certainly are; for if, on a wounded surface protected by antiseptic dressings, bacteria were to appear, then one of two things would be certain: either that the germs had entered from outside, or that they existed in the patient's organism previously. But is this the true criterion? Certainly not. In judging of the value of a therapeutical method, the one and only criterion is success. The question of primary importance is not whether bacterial germs are killed or sterilised, but whether the pathological results of septic infection are prevented, so that the wound is free from inflammation, the constitution free from fever. Consequently, whatever doubts we may be led to entertain as to the theory, those doubts ought not to interfere with our cordial acceptance of the evidence which has now been accumulated of its prophylactic value.

Some of you are probably aware that two series of observations have lately been published in Germany which go to show that, although in many instances the occlusive treatment is successful, not merely in warding off infective results, but also in the shutting out of germs, there are others in which the first object is completely accomplished—the patient remaining free from fever, pain, and inflammation—but yet organisms exist in the discharges. Obviously we might, if we chose, say, "Professor Lücke is not Professor Lister. It does not follow that, because organisms are found in the discharges from drainage-tubes at Strasburg, they should also be found at King's College." This, of course, may be freely admitted, but does not answer the objection. What is alleged is, that in these cases, although the method was carried out sufficiently perfectly to accomplish its end (the absence of pain, fever, inflammation), nevertheless organisms had found their way into the discharges; but that here, as elsewhere, being placed under conditions hostile to their development, they had been harmless.

If this be true, the inference to be drawn from it is, of course, that the treatment of a wound is not an experiment on spontaneous generation, but an experiment on infection: to use Professor Tyndall's striking expression, a combat not with atmospheric germs, but with pathological infectivity. Clearly, if it were purely a question of the exclusion of germs, the entrance of one germ would be fatal. But are there not hundreds of instances in which traumatic surfaces are exposed to germs without any effect whatever? Look at the ordinary results of the thousands of operations that are daily performed on animals for economical purposes without any precautions against germs. How often does infection occur? Not once in ten thousand times. Again, how often does it happen that an ordinary incised wound, notwithstanding that the knife that made it is beset with germs of many sorts, fails to heal straight off *per primam*? Again, in vaccination and in subcutaneous injection, do we not take every pains to do the operation in such a way as to promote absorption of whatever is on the surface of the instrument; yet who ever thinks of air-germs in connection with either of these operations? Dangers from infection, alas! attend both; but the infections we have to fear are of *pathological*, not *meteorological*, origin.

Now, these facts cannot be explained on the ground that the wounds in question are too inconsiderable; for we know by experience that, when real infection is in question, it is precisely by such wounds that it enters. For example, you will find, if you examine the records of outbreaks of hospital gangrene, that the wounds attacked were not suppurating or granulating wounds, but mere scratches or pricks.

I am desirous, in all that I say on this subject, to keep strictly within the limits of my own scope; I do not desire to make practical applications. My aim is to show that the principles which underlie the success of the antiseptic treatment are deeper than the surface of the wound. Let me, in conclusion, endeavour to indicate what those principles must be. The first principle that suggests itself on pathological grounds relates to the avoidance of conditions in the wound itself which favour the development of infectivity. Considering that the development of

infective action in a wound (supposing it to depend on the evolution of successive generations of organisms) must be a question of time, and that the circulating blood and living tissue are the most powerful colytics that we know in restraining and preventing that development, all methods which tend to prevent the accumulation of blood or liquids in wounds must be of great importance, not because these materials are in themselves incapable of being absorbed or organised, but because, if accumulated in quantities, they are withdrawn from the colytic influence of the living tissues.

The second principle I take to be the avoidance of infective contamination, in connection with which the question at once arises of the source of such contamination. If it be not atmospheric particles, what is it? Bear in mind that, wherever bacteria have been vegetating for some time in moisture containing the material for their growth (and we have seen how simple their requirements are in this respect), there infective virus is being elaborated. Consequently, that ordinary filth (of which the only scientific definition is, that it consists of the products of bacterial evolution) is more or less virulent or infective according to its development. Hence, if against all filth there lie a *prima facie* presumption that it is infective and a source of danger, scrupulous cleanliness must be essential. I need not add that, in antiseptic surgery and in the practice of those surgeons who have accomplished the greatest successes in the combat with traumatic infection, this principle is so well recognised that, in the future, we may hope to speak of "surgically pure" instruments as familiarly, and with as much significance, as we now speak of "chemically pure" substances. As may have been observed before, the colytic treatment is an importation of the methods and principles of the laboratory into the surgical ward.

But there is a third principle, which must not be forgotten. If there be any truth in what I have been saying as to the mode of origin of infective virus, the use of disinfectants, and among disinfectants of those which are known by experiment to be the most efficient colytics, must be of the greatest value. The benefits already derived from the use of carbolic acid are matter of accumulated clinical experience, and, as I have already hinted, even better results may be hoped for from other bodies belonging to the same category.

I have occupied so much time with the discussion of the origin of common, or traumatic, or phlogistic infectivity, that I have too little left for the other question I have to bring before you; namely, that of the intervention of living organisms—microphytes—in specific infection, *i.e.*, in the communication of specific diseases from diseased to healthy individuals, and in the development of the pathological consequences of such communication. This question, let me observe, although quite as important as the other, is so entirely unconnected with it, that no conclusions we have arrived at with respect to the origin of traumatic infection can be applied without reconsideration to that of *contagium vivum*. The septic poison we have seen to be an exclusive product of bacterial development, a product which bacteria are capable of manufacturing from unorganised and perfectly harmless material, a product which, although incapable of passing through certain kinds of filters, is soluble in the ordinary sense. Pathologically, we have seen that it does not act the part of a specific contagium; that, in order to the production of its morbid effects, a sufficient quantity must be introduced into the circulation; and, further, that the intensity of effect is proportionate to the quantity introduced; so that, if the amount be not too great, the tendency is to a favourable, not to a fatal, termination. But everyone knows that there occur from time to time in clinical experience instances of a sort of septicæmia of a much more virulent kind; cases, for example, of septic peritonitis, in which the quantity of the agent required to produce the fatal result is not measured by drops or grains, but (if one may so express oneself) in homœopathic doses; cases in which we at once recognise that we have to do, not with a poison of which the effect is determined by its quantity, but with a ferment of which the destructiveness to life is chiefly dependent on the rapidity of its development.

The history of these most malignant forms of septicæmia (I call it so for want of a better word) is simple enough. The gateway by which the seed enters may be, and usually is, a mere prick, and the primary effect so slight as to excite no attention. After hours, or even days, the absorbents and lymphatic glands, of which they are the tributaries, become the seat of inflammation, on which follows diffuse suppurative infiltration of the surrounding cellular tissue. Soon the process extends beyond the limb affected, to the integuments of the trunk, to the pleura, to the peritoneum; the inevitably fatal result, which is preceded by delirium and collapse, being partly, perhaps, due to the direct influence of the specific contagium, but principally to the enormous development in the organism of the ordinary septic poison.

These appalling cases must be clearly distinguished as regards their pathological nature from ordinary septicæmia. That they also have their mycological interpretation I have endeavoured to show by experiment. I have shown,\* as regards peritonitis, that if the exudation of a simple peritonitis be injected fresh into the peritoneum of another animal, the disease assumes a more intense form in the second than in the first; that if in this way the disease be communicated to several animals, the effects will differ in different cases; that if by artificial selection the most severe case be picked out and the exudation from that case be used for further transmission, a still more intense inflammation will be the result, until at last a virus is obtained of which the virulence resembles that of the specific cases of malignant peritonitis in the human subject to which I have been referring. To account for the production of such cases, you have only to substitute accidental for intentional selection, the most important point to bear in mind being that the process by which the poison is developed, whether accompanied by a specific organic form or not, is a pathological process, that is, a process which can only go on in the living tissue, and which is necessarily associated with a certain definite succession of structural and physiological changes in the affected part. To obtain information respecting these processes, we must have recourse to experimental pathology. For example, experiments like those to which I have referred, which show how, by a gradual evolution, we may rise from common traumatic infectivity to the intensified virulence of malignant septicæmia, teach us what we could not learn otherwise.

From these cases, in which the direct intervention of a morbid organism is merely a matter of inference, I pass to the consideration of the only instances in which we are, at the present moment, able to say with confidence that we know the relation between morphological and pathological development. When I last had the opportunity of addressing you on the subject of contagious diseases, I enumerated four such diseases as the only ones in respect of which we are able to assign any pathological meaning to the organic forms which present themselves in the diseased parts. With reference to three of these, namely, relapsing fever, diphtheria, and small-pox, some new facts have been brought to light during the last two or three years; but before I refer to them, I will bring before you the very remarkable discoveries relating to the origin and development of the fourth member of the group—the epizootic anthrax of cattle—which have been made during the last year by a pathologist with whom I have lately had the pleasure of making acquaintance, Dr. Koch of Wollstein, in North Germany.

In my former lectures, and more fully in a paper which has been published in the *Reports of the Medical Officer of the Privy Council*, I gave an account of this remarkable disease, which I then called by the English name splenic fever. A still fuller description of the disease is now in the hands of English readers in Professor Bollinger's article in Ziemssen's *Cyclopædia*. It is a disease of great rapidity, of which the prominent symptoms strikingly resemble those of septicæmia. Excepting in very rapid cases, which are often spoken of as apoplectic, a previous febrile stage may be distinguished, but in bovine animals death is preceded by alvine discharge and gradual loss of temperature. After death, the pathological appearances somewhat resemble those of septicæmia, in so far that capillary hæmorrhages occur in the affected parts, and that there are signs of disintegration of the blood-corpuscles and that the blood fails to coagulate after death; but there is this difference, that the disease exhibits special localisation, in some cases in the subcutaneous cellular tissue, in others in the submucous tissue, the change consisting in abundant discharge from the vessels of liquor sanguinis and of corpuscles. The existence of these infiltrations and the fact that the spleen is always intensely congested and swollen, constitute the naked-eye pathological characteristics of splenic fever. The facts which were known in 1874 relating to the propagation and essential pathology of splenic fever are fully stated in my paper.† Let me enumerate them: 1. The blood of a diseased animal communicates the disease by minimal inoculation to a healthy animal; 2. Such blood always contains, when in some stage of the disease, certain characteristic organisms—the so-called bacilli of anthrax; 3. Blood which has been filtered through porcelain is not poisonous; 4. Blood taken from animals in the acute stage cannot be kept for more than a week without losing its activity; 5. Notwithstanding this, there is evidence that in certain forms the poison is very persistent.

I suggested that this last fact could be explained by supposing that the organism (for here I may state by anticipation that I then regarded it, and still regard it, as completely made out that the specific pathological process is inseparably associated with the organism) that the organism is capable of existing in two states similar to those which we

know to exist in other cases, in one of which it undergoes rapid development but is of labile molecular structure; in the other, it is permanent and resistant.

My friend Dr. W. Roberts has complimented me on having anticipated the results of the investigations of this year. I cannot claim any special credit for this, for the indications afforded by the facts were too plain to be mistaken, so that I could scarcely fail to be right in my inference, if I paid sufficient attention. Knowing what I knew of the life-history of the group of organisms in question, it was not difficult to anticipate that, if such an organism existed, it must behave in the way suggested. Its development must be made up of an alternation of labile and stable states of existence—lability corresponding with rapid vegetation, stability with the apparent suspension of all those changes of the vital process which constitute life. The credit in such cases is due, not to the man who imagines how the thing is likely to happen, but entirely to the man who demonstrates what does happen by experiment or clinical observation. In this case, we must give it entirely and exclusively to Dr. Koch, who has proved experimentally that the blood of animals affected with splenic fever in its most acute form loses its activity very rapidly, but that certain kinds of blood may be kept for long periods, e.g., of years. The contagious material must, therefore, exist in the blood in two forms. Blood which possesses the power of resisting contains, he says, not only the peculiar motionless sticks which are found in the blood and particularly in the enlarged spleen, of every diseased animal, but also certain oval glistening bodies which, from their mode of origin, Koch is justified in calling spores. The way in which the proof is given that they are so is the following. If you take the blood of an animal in the acute stage of the disease and cultivate it in serum at the temperature of the body, the organism begins at once to vegetate rapidly.\* This growth does not, however, consist in multiplying of the sticks by division; for, on the contrary, the sticks prolong themselves into filaments of great length in which no divisions can be distinguished. Next a change takes place in the structure of the internal substance of each of these filaments, by virtue of which the protoplasm collects itself at certain points into masses. As time advances, these masses become more and more distinct, assuming finally the form of round or ovoid spores. Eventually, the filament fades away and the spores are liberated.†

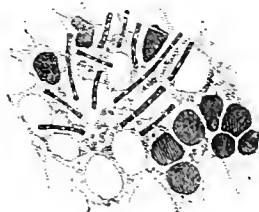

Fig. 1.

Fig. 1.—Bacilli, as seen in a fresh preparation of an animal affected with splenic fever. The blood-corpuscles and bacilli are deeply stained by an aniline solution, which has been added for the purpose.

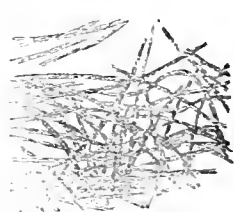

Fig. 2.

Fig. 2.—Felt-work of long unjointed filaments, into which the rods grow when transferred to humor aqueus, and kept at a temperature of 32 deg. C.

Fig. 3.

Fig. 3.—The same filaments twelve to twenty-four hours later. The formation of "spores" in their interior has already commenced.

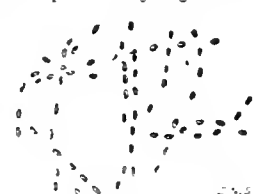

Fig. 4.

Fig. 4.—The spores in their complete stage. Some are free, but the most are still held together by the scarcely distinguished remainder of the filaments. The infecting power of these spores has been recently tested in the course of experiments now in progress.

\* Dr. Ewart, of University College, has during the last few weeks been engaged in studying the development of the bacillus, and has been able to add very considerably to the facts relating to its development. The summary I give in my lecture is founded on the observations in which I had the opportunity of taking part, through the kindness of Professor Cohn and of Dr. Koch, in the laboratory at Breslau. I will not anticipate Dr. Ewart's results, which will, no doubt, be soon published. It is sufficient to say that they are of such a nature as to fix the morphological specificity of the anthrax plant with even more certainty than before.

† The figures have been copied from Dr. Koch's photographs, published in Professor Cohn's *Beiträge* since the lecture was delivered. They will serve to render the statements I have given more intelligible.

\* *Medizinische Jahrbücher*, vol. vi, p. 417; and *Journal de l'Anat. et de la Physiologie*, July 1876.

† *Reports of the Medical Officer of the Privy Council*, new series, No. 8, p. 36.

It is these spores which contain the element of resistance. I shall be able at our next meeting to show you preparations illustrative of their development. Since the publication of Dr. Koch's paper, they have been studied by M. Pasteur, who states that they are not only resistant to putrefaction, but also to the boiling temperature and to the action of oxygen under high pressure.\* M. Pasteur further states that he has cultivated them in urine for very long periods, and has found that they retain their virulence after repeated cultivation. In a pathological point of view, the importance of the whole research lies simply in this: that to a liquid, which is in itself harmless, viz., serum or aqueous humour, properties can be communicated by setting up in it a process of vegetation, of which the effect is that a virus is produced—a virus which has no relation to that of putrefaction, and acts in a specific—that is, peculiar, way; its action being to multiply with extraordinary activity in the blood and tissues of the living animal, and by virtue of such multiplication to destroy life.

I am anxious to place before you the facts which we possess in relation to splenic fever in the strongest light, in order that it may be clearly seen that the conclusion we are compelled by these facts to arrive at, in respect to this disease, is based on evidence of an entirely different nature from that on which the general theory of *contagium vivum* is supported. If I come forward and assert, as a matter of scientific observation in respect of any substance, whether a chemical body or an organism, that it is a virulent contagium, you have a right to require of me to prove it, not by referring to analogies or to the condition of its origin, but by experiment. And in this experimental proof two things must be included: first, I must show you that if I introduce it into the organism of a living animal in minimal quantity, it will sooner or later become the focus of a pathological process; and secondly, I must prove to you that the virulent substance which thus acts in producing the specific disease, is itself a product of that disease, that is, that it can be obtained directly from the body of the diseased animal. It is on this ground that we proceed whenever we rightly apply the term contagium. Thus, in the case of vaccine, we correctly apply the term to vaccine lymph, because, on the one hand, it is a product of the process of vesication; and, on the other, produces with certainty a vesicle. In a word, it is at the same time a seed and the fruit of the disease. As regards cow-pox, therefore, we have the most complete certainty as to the existence of a contagium, and have it, as it were, between thumb and finger. Of its nature we know nothing as yet, excepting that it is particulate. As regards the question whether these particles possess organic structure or not, in other words, whether they possess the power of vegetative development which is associated with their morbid action, we know absolutely nothing. That organisms are present is certain enough, and that they are peculiar, but of their function nothing has as yet been ascertained. Mr. Godlee's experiments, which, as regards skill and accuracy, left nothing to be desired, go to show that the organisms which are always found in the liquid fail to afford evidence of their pathogenic properties. The same remarks apply to the organism of small-pox. Another similar example is that of diphtheria. It is perfectly certain that, in every case of faucial diphtheria, a mycotic process goes on in the affected mucous membrane; in other words, that the vegetation of micrococci is an element in the peculiar inflammation which gives rise to the diphtheritic concretion. And inasmuch as, from clinical observation as well as experiment, we know that the concretions contain in themselves the specific contagium, it is impossible to dispute that in every case in which the disease is communicated by contagium, that communication may take place through the organisms, but the proof is as yet entirely wanting.

With reference to both diseases, I mean both to small-pox and diphtheria, we have evidence of another kind, which is of great importance. Although the two have little resemblance, they correspond with each other in this respect, that both are followed by secondary affections in internal organs—that in both it is the same organs which suffer, viz., lungs, liver, kidneys, and heart. As regards diphtheria, an excellent description of them, founded on cases, has been given by a French writer, M. Labadie-Lagrave,† but without histological details. The most remarkable of these lesions, and the one which is of most interest in relation to our present inquiry, is the valvular endocarditis, which, according to M. Lagrave, occurred in more than half of the forty-six fatal cases under his observation. Now, this affection, of which, as a complication of diphtheria, he has given a good account, is the same as the "ulcerative endocarditis," which was described, perhaps for the

first time, by Dr. Kirkes, and has subsequently been noted by others in various infective diseases, particularly Dr. Moxon,\* by the late Dr. Fuller in erysipelas, by Dr. Dickinson in pyæmia, by Trouseau, and, if I am not mistaken, by Dr. West in scarlatina, by Wunderlich in measles: and has been recently more completely studied by Dr. Heiberg† in puerperal pyæmia, and by Dr. Weigert in small-pox.‡ Now, in all these cases the endocarditis has a doubly infective character. It is itself the consequence of an infection, and the focus from which infection spreads; for it appears to be closely associated with affections of the kidneys, liver, and lung, which exhibit such characters as might well be accounted for by supposing that minute portions of infective material had become free from the diseased valves, carried away by the blood-stream, and thus disseminated in the affected tissues. The endocarditis presents itself in two stages. The early stage, in which what is seen is that the edge of the valve (usually, but not always, the mitral) is beset with a little chain of greyish miliary elevations on a redder ground; and a later stage, in which a process resembling ulceration has occurred, in which evidently the material forming the nodules has disintegrated.

The whole subject of infective valvular endocarditis and its concomitant disseminated affection of other organs requires a great deal of study, and I do not know any subject at the present moment more worthy of clinical and pathological investigation. But the point that I have now to bring under your notice is that, in the only diseases in which the lesions have been investigated anatomically, pyæmia and small-pox—in the former by Heiberg, in the latter by Weigert—it has been found that the affection of the valves is mycotic, that is, that the thickening of the endocardium which takes place—a thickening which has its seat in the intima—is associated with the development of colonies of micrococci; and, further, that the punctiform foci of dead alive material which occur in other organs are not minute abscesses, not foci of inflammation, but spots where localised tissue-death has occurred in consequence of little masses of the same kind which have either migrated from the affected valves, or quite as probably have found their way from the lymphatics of the affected skin—those vessels being in the early stages of malignant small-pox to a greater or less extent, occupied, as Dr. Klein and Dr. Weigert have shown, with the same organisms. In its bearings on the notions we must entertain as to the action of micrococci in the organism, these disseminated foci are of great interest and importance, for they show two things very plainly, viz., first, that, although ordinary bacteria cannot live in the circulating blood, yet there are organisms allied to these which can live and thrive after their own slow way—organisms which do not exhibit either the miraculous prolificness or the active motions of septic bacteria, but grow together in colonies of motionless spheroids; and secondly, that, when such organisms are present, they produce very little irritation in the tissues with which they are in contact.

The observations of Weigert show conclusively that the effect of the dissemination of these masses is not to produce foci of inflammation, but simply of necrosis. In the first instance, whenever the opportunity offers itself of investigating the lesions in its earliest stage, it can be made out with respect to each mass of micrococci—1. That it is enclosed in a vascular cavity; and 2. That it is surrounded by a zone of altered tissue, within and around which, although the elements have undergone a peculiar kind of degeneration, there are not any inflammatory changes. Eventually this island of altered tissue becomes the seat of cellular infiltration, and you have before you what may be termed a miliary abscess, but even then it is still possible to demonstrate in the centre of each such abscess the original mycotic nucleus.

What do we learn from this? 1. That, in certain infective diseases, of which erysipelas, diphtheria, and small-pox may serve as examples, the preliminary local processes which constitute the essential feature of the local lesions, whether primary or secondary, are associated with, and in great measure consist of, the development either in lymphatics or in blood-vessels of micrococci. 2. That these organisms have little or no resemblance to the bacteria of septic processes, being distinguished from them by their form, but chiefly by their mode of growth, that is, by the circumstance that they grow in rounded masses or colonies. Although obviously connected in their development with infective processes, they do not in the slightest degree resemble the infective organism of splenic fever. They show no tendency to multiply in the cir-

culating blood, nor, indeed, to spread their influence at all beyond the tissues in which they have taken up their residence.\* They are associated in every instance with local, not with general, processes—with processes which spread by continuity of tissue, not with general infection of the whole organism. What the nature of that relation is, I still think, as I thought when I last had occasion to speak on this subject, must remain open. The view which commends itself to my mind as by far the most probable, is that, whatever may be the original nature of the primary disease in association with which they present themselves, the organisms are specifically the same; that they reciprocally are modified by, and modify the soil in which they find themselves, and, by virtue of this interaction, take as important a part in the secondary processes to which they belong as pus-corpuscles take in the process of inflammation. Whether they are in any respect entitled to be regarded as specific contagium particles, whether they possess the power either of conveying the contagium from a diseased part of the organism to a healthy, or from one diseased body to another, we are still bound, I repeat, to regard as an open question.

## CLINICAL LECTURE ON PHLEBITIS.

By WILLIAM S. SAVORY, F.R.S.,  
Surgeon to St. Bartholomew's Hospital.†

THE phenomena of phlebitis—its symptoms—are comparatively simple, and for the most part sufficiently clear. The disease often starts with pain—or, perhaps, more accurately speaking, aching—and acute tenderness in the course of the affected vein, which in the majority of instances, I think, at the outset presents to the touch evidence of being plugged. At other times, beyond perhaps an aching of the leg or other part, the only local evidence of the mischief is œdema. But this is usually, I think, very significant. The œdema of this affection is firmer, and apparently more generally diffused throughout the limb, than when it is due to simple obstruction or failure of the circulation. The affected limb, or part of it, is enlarged and thickened, but often with comparatively little alteration of shape, the skin pale and tense, and, when the part is grasped, the texture feels uniform and solid. One misses the characteristic pitting, upon moderate pressure, of ordinary œdema. The whole condition of the limb seems one rather of the state in which it is often left after an attack of phlegmonous erysipelas. And it seems to me important to distinguish between these two classes of cases: those which commence with local pain and tenderness, and those which are marked only by œdema; for, in the former case, the superficial veins only are at fault; in the latter, the deeper veins.

Take this case. Ernest C., aged 26, a barman, of dark complexion, well built, although inclined to be fat, and strong, was admitted into the hospital in the following condition. The right foot, leg, and thigh are much enlarged by firm œdema. The right thigh in the middle measures  $23\frac{1}{2}$  inches, the left  $20\frac{3}{4}$  inches. The skin is very tense and somewhat injected, and above the right ankle in the lower half of the leg it is eczematous. This part, he says, was the seat of an ulcer two years ago. In the upper part of Scarpa's triangle, in the position of the femoral vein, a hard and tender cord can be felt on deep pressure. There is also slight tenderness over the iliac fossa. The epigastric veins are conspicuous. He told us that, nearly two years ago, after a long boat-race, he noticed that the veins of the right thigh were prominent. Three or four months later, he found one day, after hard work, that the right ankle was swollen, but on the following morning this had subsided. From that time, however, the foot and ankle were often enlarged, and the swelling gradually extended upwards, so that for the last year the leg, knee, and lower part of the thigh were markedly larger than on the left side. His health was not affected until just previously to his admission, when he began to suffer pain along the course of the femoral vessels, and then the whole of the right limb became much swollen and very tense. He admitted that he had drunk freely of beer, and had syphilis six years ago. For some days after his admission, the pain disturbed his rest. His temperature rose from  $101.8$  deg. to  $103.6$  deg. The swelling of the thigh increased until it measured at the middle  $25$  inches. On the fourth day after admission, he had four attacks of epistaxis and one was copious. His temperature fell, and the next day it was normal. During the following week, the swelling

of the thigh subsided, until, at the expiration of a fortnight from his admission, there was very little difference in the size of the two limbs. But, for a week or two longer, a hard cord could be distinctly traced through Scarpa's triangle. He was kept in bed with the limb still. Strong lead lotion was applied at first, and afterwards a flannel bandage.

I may, perhaps, be allowed to publish the following note, which I made when I worked in the out-patient room of the hospital. I have seen, within the last twelve or fifteen months, eight or ten cases of this description. A person previously in tolerably good health, or at all events having no definite cause of complaint, is rather suddenly seized, without any obvious reason, with diffused pain in the calf of the leg. The pain, which is usually severe, is soon followed by a sense of extreme tension and by swelling, which, for a few hours or a day or two, gradually increases. When the leg is examined, the whole of it below the knee to the ankle is considerably swollen, tense, and very tender about the calf. In some cases, the induration is very marked. The surface will hardly yield to firm pressure. There is no elasticity, but a sense of hardness, as if something had been effused into the cellular tissue which had set and rendered the whole solid. By-and-bye, or in some cases from the first, the hardness is more circumscribed, and limited to the calf. There is never at first, and often not throughout, any discoloration of the surface. It is usually pale, tense, and somewhat shining. In favourable cases, the whole will gradually, almost imperceptibly, subside, and the limb resume its natural condition. In others, a sense of fluctuation gradually arises in the thickened and indurated calf, and this is followed by a blush on the surface. An incision, in these circumstances, will let out a considerable quantity of well-formed, but usually more or less blood-stained, pus.

With all this, a careful examination will in most cases fail to discover any morbid or unnatural condition of the veins of the limb. The femoral and superficial veins will appear natural. In some cases, however, the femoral vein is obviously thickened and tender, and can be traced as a cord through a portion of the thigh. There is usually little or no constitutional disturbance. Where the opportunity has been given, of course, the patients have been kept at rest; but, in more than one instance, they have continued to attend at the out-patient room, even walking to and fro, yet all has gone on well—in these cases it has happened without suppuration—and the limb has been restored.

Now, what is the pathology of these cases? Looking at their history and the features they present, I regard the veins as the primary seat of mischief. That the femoral vein itself is involved in some of the cases, is a matter of certainty. And those cases in which all the veins in reach of the senses appear normal, so closely resemble the others in which the veins are obviously at fault, that it is impossible not to refer them to one and the same pathological cause. If any opportunity of dissection were afforded me, I should expect in these last cases to discover something wrong in the deepest veins. I will not venture at present, on such slender evidence, to speculate further on the pathology of these most interesting cases. It is difficult to explain all the changes that ensue by simple venous obstruction, even though that were general; and, assuming this to exist, I could only guess at the cause of it. The cases are striking ones, and form a distinct class. That their pathology involves some change in the veins, I strongly believe. Beyond this, I dare not go.

Again, when the veins affected can be traced, the extension or course of the disease may be observed in two forms. There may be a simple extension, either gradual or rapid, of the pain, tenderness, solidification, and distension in the course of the affected veins; or these local signs may exhibit a striking want of uniformity. They may shift from vessel to vessel, or from one portion of a vessel to another, and in this way wander irregularly over the surface of the limb; subsiding in one part and starting afresh in another; fluctuating from week to week, or even perhaps from day to day, but withal obstinately inclined to linger, and to disappoint us of expected convalescence. Paget says of gouty phlebitis: "In such cases, the phlebitis may have no intrinsic characters by which to distinguish it; yet, not rarely, it has peculiar marks, especially in its symmetry, apparent metastases, and frequent recurrences" (*St. Bartholomew's Hospital Reports*, vol. ii, page 83.)

Here is an instance. E. C., about 50, was a stout, heavy muscular man, abstemious, very active, and in apparently good health. He had suffered, however, two or three times from "rheumatism in the knees and legs", once rather severely, for which he sought relief from the mud-baths of Marienbad, which "always cured" him. In both legs, below the knees, the veins were somewhat varicose. He came complaining of pain in one leg, and there was an oval dusky patch, branny to the touch, as large as the palm on the inside in the middle third. The tortuous internal saphena vein was very tender, somewhat thickened, and here and there apparently solid; but, in the midst of the thickened tissues, it could hardly be defined. This continued to trouble

\* In this and the preceding statements relating to small-pox, I have followed Dr. Weigert, who was good enough to show me his preparations when I was in Breslau last October.

† Concluded from page 149 of last number.

him for two or three months. The surrounding disturbance in the skin and cellular tissue, with rest, speedily subsided; but the vein, the outline of which became sharper, remained painful, tender, and solid; the mischief fluctuating in severity and extent, sometimes extending in one direction while it subsided in another. He declared throughout that his general health was excellent, and he would complain of nothing beyond what he called the nuisance in his leg, and I could not discover anything further amiss with him.

Here is a very slight case. A spare active man, of fairly moderate habits, whose health had always been excellent, with the exception of rare and transient pains which he called rheumatism, discovered one morning in his bath that a spot on the inner aspect of the thigh, just above the condyle, was tender. Here I found a portion of the internal saphena vein, for two or three inches, plugged. He was astonished to hear that there was anything amiss there, was sure that it was not due to injury, and could hardly be brought to believe that the matter merited any attention. No amount of cross-examination could elicit evidence of anything further wrong. The mischief never extended, and the pain and slight swelling and tenderness slowly subsided with rest. His health has remained good, and he has never since been troubled in that or in any other way.

I have often been surprised in noting with how little constitutional disturbance this affection, even when severe and extensive, is accompanied. Nothing may be observed beyond a trifling and transient rise of temperature, and often even this is absent. There are exceptions, of course, and sometimes grave ones; but, as a rule, in these cases the patients neither show the signs nor complain of illness, and oftentimes one of our chief difficulties is to ensure rest. Persons cannot understand the importance we attach to what frequently seems to them a trivial affair; and become impatient of confinement. Of course, as in the rheumatic or gouty form of the affection there may be special indications of constitutional mischief. But even when we may be disposed to suspect strongly that a particular cause of this kind is at the root of the evil, it is sometimes difficult to elicit anything like clear evidence of it; and we must be, and perhaps too often are, content to believe without a reason.

Take the following instance. George B., aged 37, a fair, lean, ill-nourished man, a leather-cutter, was admitted on April 26th, 1877. He had suffered since the beginning of the year from pain in the left foot and leg, with some swelling. In February, he was laid up in bed for some weeks, and at this time his right foot and leg became similarly affected. This was supposed to be rheumatism. But at length the pain passed upwards to the inner side of the right thigh. He slowly recovered. The left leg became painless and natural, but some swelling of the right ankle remained. He went back to his work, and then the mischief in the right limb soon returned. Now there is oedema of the right foot, leg, and lower part of the thigh, and the distended skin is somewhat reddened. In Scarpa's triangle, the femoral vein is hard and distended, and near Poupart's ligament tender. There is no obvious distension of the superficial veins. Temperature 98.6 deg.; pulse normal. He told us that, in the previous August, he had a similar affection of the left internal saphena, but otherwise he had always enjoyed good health. His father died of consumption. Two sisters are living and healthy. There was no family history of gout or rheumatism. For more than a month he lay quiet in bed. The limb was slightly raised, and after awhile a flannel roller was applied. The signs of local mischief gradually disappeared, and his health was not disturbed. At the end of that time, no unnatural fulness could be discovered in Scarpa's triangle.

A rather stout man, with muscular limbs, very abstemious, the veins of whose legs had been for years somewhat varicose but without trouble, and who considered that he had always enjoyed excellent health, complained one evening of pain over the surface of the right tibia. Upon examination, a small tortuous vein there was found to be exquisitely tender, but soft and otherwise apparently not unnatural. The pain, however, continued and rather extended, and soon the vein became full and prominent, but not sensibly hardened. This lasted some days, when the mischief gradually crept over some of the veins of the inner side of the calf. These gradually became distended, and apparently filled with soft clot. Then the pain and tenderness on the vein first attacked slowly subsided; but presently a cluster of veins on the outer side of the calf fell into mischief, following a similar course. And so for weeks the trouble wandered about the saphena veins and their branches in the leg; but never appearing above the knee, except in one doubtful spot to the inner side of the saphena opening. As the fulness and tenderness passed away, the portion of vein was left apparently plugged, and each fresh accession of mischief was attended by no effects beyond those of the part involved. There was no oedema, no pain, when the limb was at rest and not touched, and his health

throughout was apparently so good that he only suffered from the enforced rest. He acknowledged, however, the comfort of keeping the limb quite quiet, with the foot somewhat raised.

Now, when this affection is established, what may be its course and result? This question opens the most interesting part of our inquiry.

The great majority of these cases terminate in recovery, and the recovery is usually at length complete. All evidence of any clot or plug in the vein is gradually lost, the vessel becomes natural to sight and touch, and all signs of any obstruction to the circulation through it disappear. What becomes of the thrombus? It is said to be absorbed. Where, and by what means? That we hardly know. What change does it undergo previous to disappearance? If much time elapse, it shrinks and contracts, and probably degenerates after the fashion to be noted presently.

Often, however, the vein remains permanently thickened. It is unnaturally rigid, and can be traced in this state for some distance along the limb. In most of these cases, there is probably only a partial restoration of the current through it. The clot in the interior does not wholly disappear, but very slowly shrinks and condenses into a structure more or less distinctly fibrous, which either forms a layer of variable thickness lining the whole of the surface, or it contracts into an irregular cord, which lies in contact with only a portion of the wall, the rest being free. Our museums contain many specimens of this kind: Veins with their walls either natural or rigid and thickened, with fragments of clot in the interior, variously shaped and arranged; of course obstructing the canal; many of these, by their structure and other characters and history, being clearly very old. A corrugation and apparent thickening of the vein-wall, due to contraction of a clot attached within, must not be confounded with the condensation and rigidity of the vein-wall, which is due to inflammation. In the former case, the vessel can be restored to its natural state by injection. Callender (*System of Surgery*, 1870, vol. iii, page 366-7) has clearly pointed out this. Moreover, these old clots sometimes acquire a very intimate connection with the vein-wall. Some of them may be stripped off or easily detached, and the surface of the vessel beneath may present little or no change. It may appear less polished, and the endothelium may have disappeared; but at other times the union is so firm that the clot cannot be separated without laceration, either of its texture or of the vein; and in certain rare specimens the two structures appear to be directly continuous. Organisation of the clot is an expression very often employed. What does this mean? When used in any definite sense whatever, very different ideas are by different pathologists attached to it. If it mean that the clot has acquired a fibrous structure and is permanent, then very many clots become organised; but if it mean that the clot has become continuous with the wall of the vein and possesses intrinsic blood-vessels, then organisation of the clot is beyond doubt a very rare event; and if the fact of its occurrence be disputed, it is not easy to produce satisfactory evidence of it. So far, therefore, as the effect upon the vein and its circulation is concerned, we find in these clots all degrees of duration and of obstruction. So, too, in the effect produced upon the limb. There may be no perceptible oedema throughout, or the whole limb may be converted into a huge unshapely appendage. When the oedema is considerable, or, indeed, oftentimes even when comparatively slight—as we should expect from its solidity—it only very slowly disappears. It may endure for very many months, hindering exercise, and otherwise producing much inconvenience, and making convalescence a very tedious process. Nay, sometimes the limb never after recovers its natural size or shape, for the tissues remain permanently infiltrated and hard. I say infiltrated, but frequently the cellular tissue seems to have overgrown; and with this actual increase of substance, there is much condensation. It is not only the subcutaneous tissue which may be thus affected. The change may have passed throughout the whole limb; to the connective tissue along the track of the great vessels, and between the muscles, and even into the substance of the muscles themselves. Sir James Paget tells us that even the muscle-tissue itself—the contractile substance—is hypertrophied; and that, in this way, the limb may become actually stronger than before.

A varicose state of the surrounding veins is not often seen, in consequence of thrombosis. They are far more frequently dilated, tortuous, and overgrown, from obstruction due to other causes, as from the pressure of a tumour. This may be because the larger veins are hardly ever permanently obstructed by thrombosis.

You will readily understand that there is the widest range in the extent to which the veins may be plugged. The whole mischief may lie within an inch, or it may extend throughout large tracts of the venous system, spreading in all directions from the vessel first affected, but especially towards the heart. Starting, for example, in one of the saphena veins, it may pass on into the femoral, iliac, and vena cava;

and no one needs to be told with what interest and anxiety its onward course is watched. It may prove fatal in this way, but I do not think it often does. When the largest veins are reached, the case is indeed grave enough, the peril obvious; but even then, without accidents, patients will escape. I think I am justified in saying that we regard these cases, even of very extensive plugging, more hopefully as we become more familiar with them. And the accidents of phlebitis, of which I have yet to speak, are, I think, comparatively less frequent than they were formerly supposed to be.

But, the clot once formed, may change in another way. It may undergo degeneration. And the study of this degeneration of clots in blood-vessels and its consequences cannot, I venture to say, be surpassed in interest and value by that of any other subject within the range of pathology or surgery. Even the history of our present knowledge of the process is singularly attractive, and I am sorry that there is no excuse for introducing it here. I have already said of the term suppurative phlebitis that, in the sense in which it was formerly used, the phrase no longer prevails. For Gulliver, first of all, and afterwards Virchow, showed that, what was formerly regarded as pus, is the liquefied product of the degenerated blood-clot. This, for obvious reasons, usually begins and is found most advanced in the centre; and while the crust of the clot still retains its integrity, an appearance is presented as of an abscess circumscribed by a wall of lymph, and thus the "pus" is shut off from the general circulation. Here is the old "circumscribed suppurative phlebitis". But at length the whole substance of the clot may liquefy, and the "pus" may then spread along the course of the vessel and become diffused in the blood. The old "diffused suppurative phlebitis". Now substitute "puriform" for "purulent", "pus-like" for "true pus", and, although the old pathology must be revised—the former explanation of the cause and course of the changes being no longer tenable—the description of the phenomena in this stage of the affection will still hold good.

But now proceeding, we come to a yet larger question. What is the consequence of this diffusion of liquefied clot into the blood? Virchow, when he overturned the idea of diffuse suppurative phlebitis as the cause of pyæmia, insisted nevertheless that the cause of pyæmia is the escape of the products of degenerated clot into the circulation; that still, therefore, pyæmia springs out of these changes, consequent on mischief in the veins. Now, when blood-clot breaks down, and its fragments or *débris* mingle with the blood, that infarction of distant vessels results there can be no doubt. And it can be easily understood how this embolism will vary in its characters and effects. If the detached fragment be large and coherent, a large artery, such as one of the chief branches of the pulmonary, may be plugged, and instant death may be and often has been thus produced. If the clot have so softened as to become puriform before its diffusion, then results capillary embolism in the lungs or elsewhere; and not immediate death, but severe disturbance, provoking very grave consecutive mischief, but still, at first, local; and leading to changes in the parts affected—to inflammation and supuration, or perhaps gangrene—to which different observers have applied different terms. But with all this, not necessarily, or even commonly, I think, pyæmia. That pyæmia may thus arise, I do not deny. The changes just sketched may be set down as one of its causes; but I submit that there is not evidence enough to show that there exists any special or peculiar relation between the mischief in the veins and pyæmia as cause and effect. The error of this view has, I believe, arisen from concluding that because both affections, phlebitis and pyæmia, are apt to lead to capillary embolism and its consequences, therefore, when there is evidence of secondary mischief, pyæmia must exist. But some one will say: What, after all, is pyæmia more than this? The embola due to scattered blood-clot are local affairs—local at first, at all events; there is no evidence at this time of septic action on the blood; and if it should supervene, the general mischief follows on the local. But, in pyæmia, or septicæmia, or blood-poisoning proper, from the moment that the poison mingles with the blood, there is striking evidence of profound disturbance of the whole system, of which the local mischief in various parts is only the outcome; and I venture to think that the exalted temperature, rigors, and sweats are due to something more than infarction of a few capillaries. But now I must resist the temptation of further discussing this engrossing subject, and be content with referring those who care to pursue it to some of the earlier volumes of our *Hospital Reports*, where I have endeavoured to set forth some of the evidence from which this view is taken. Thrombosis and phlebitis, then, may be associated with pyæmia, yet pyæmia is often seen when these cannot be discovered. When these several states coexist, they may be, and in such circumstances usually are, the effects of a common cause—of a process which, acting locally, coagulates the blood in the vessels, and leads to inflammation of their walls; and, acting generally, gives rise to septicæmia.

I can well remember, years ago, when the doctrine of Virchow was dominant, with what anxiety these cases of phlebitis and thrombosis were watched; how from hour to hour pyæmia, with all its terrible phenomena, was expected to supervene. But now this is, for the most part, changed. We watch anxiously for signs of embolism, and we do all we can, by enforcing rigid rest, to guard against its occurrence; but we do not anticipate pyæmia. Still, although even the occurrence of embolism in any of its forms is exceptional, I would earnestly advise you always to act as if it were imminent in every case. Fortunately for his peace of mind, the patient does not see this sword of Damocles; but you must never forget that it hangs over him. (Let me give you one or two examples of its fall.)

A man aged 40, who had always enjoyed robust health, had been confined some weeks to his room and couch with thrombosis of the femoral vein. One evening, after his servant had assisted him into bed, he asked his master if he could do anything more for him before he left him for the night. "No, thank you", was the answer; and, giving the affected thigh a slap with his open hand, he added "I shall be able to help myself now." Before the man could leave the room, he heard the sound as of someone choking, and, looking round, he saw his master fall back and suddenly die. There was no examination, but the cause of death was obvious.

In the catalogue of our museum, two preparations in Series 13 are thus described.

"No. 132. A clot, which was removed from the pulmonary artery of a woman aged 33, who died suddenly from syncope nineteen days after delivery of her third child, having apparently progressed favourably up to that date.

"The clot measures three inches in length, and about one in diameter. One extremity, that which was towards the heart, is smooth and conical; the opposite is hollow, with ragged edges, leading into a cavity which occupies the greater portion of the interior, and is partially filled with grumous rust-coloured fibrine. It appears as if the clot had been gradually softening and disintegrating from the interior. The exterior is of a deep orange colour. Its structure presents no trace of lamination."

"No. 153. Another and smaller clot, *in situ*, from the opposite lung in the same case. It measures two inches and three-quarters in length and half-an-inch in diameter. Its extremity is rough and conical. It completely fills one of the primary pulmonary trunks, being continued into three branches by forked extremities. Of these, two, like the main clot, are firm and solid; the third is soft and pulpy."

These preparations alone might form the subject of a long discourse. Observe the evidence of disintegration of the embola and the suggestions of secondary embola consequent on this in the more minute branches further on.

Thomas E., aged 32, a dustman, was admitted into the hospital in the autumn of last year with simple fracture of both bones of the left leg in the middle third. He did well, and went to Highgate in September. But in November he was readmitted with periostitis of the left tibia about the seat of injury, and effusion into the left knee-joint. In a week, the effusion had almost disappeared and all the tenderness from the tibia, but some thickening remained there. He was allowed to get up. But, in the course of three or four days, he complained of pain in the left inguinal region and in the course of the genito-crural nerve. There was also retraction of the testicle. Then, upon further examination, a firm cord could be traced through Scarpa's triangle, and there was evidently thrombosis of the left femoral and lower part, at least, of the external iliac vein. This was rapidly followed by considerable œdema of the whole leg. The temperature rose to 101 deg. His rest was much disturbed. In the course of the week, an erythematous rash appeared on the chest, neck, and arms, and he complained of pain between the shoulders. The temperature then was from 99.5 deg. to 100.6 deg. The swelling of the left leg gradually subsided, but he complained of pain in the other leg and in the lower part of the abdomen. So matters went on for another week, when he complained of frequent chills, and there was marked tenderness over the femoral vessels. But the temperature was normal. Then, for a month or more, he gradually improved. He complained less, and the local tenderness and œdema of the limb slowly passed away. One day, three months after his second admission, he was allowed to sit up to have a warm bath. The day following, he was rather suddenly seized with great oppression of breathing, and he repeatedly spat small quantities of bright blood. The sputa were very offensive, and he complained of much pain between the shoulders. Temperature 100 deg. In this state, he was seen by Dr. Andrew, who found about the region of the left scapula diminished respiratory murmur and crepitation. The diagnosis was pulmonary embolism. For three or four days, these symptoms persisted; he continued to cough and to spit

blood. But gradually the sputa lost their odour and changed to blood-stained mucus; the temperature became normal; and in about a fortnight all the signs of this mischief passed away; and there remained only some slight swelling of the left leg and thigh, with scarcely any perceptible thickening in the course of the femoral vessels. In another fortnight, there was little to be observed beyond weakness and considerable depression; and, at his own wish, he left the hospital.

Pyæmia, then, as a consequence of phlebitis, is so exceptional that we hardly think of it as among the dangers to which our patient is exposed. The possible or probable occurrence of embolism is a source of far more immediate anxiety, but even this accident is comparatively rare. The majority of cases of thrombosis and phlebitis escape without it. The consequences of this affection are usually from first to last local—that is to say, limited to the vein or veins affected, and to the limb in which it occurs. Any direct evidence of disintegration of the clot within the vein is, for the most part, wanting. As a rule, all we are able to trace is the very gradual disappearance of the signs of thrombosis. The vessel, which at first is tender, distended, and solid, gradually becomes less sensitive to the touch, then reduced in size, but withal firmer and more cord-like; then, week by week, this solid passive cord becomes less and less distinct. The cases are very exceptional in which it remains completely and permanently plugged. No doubt, far more frequently the whole of the clot at length disappears; but, perhaps, in the majority of cases, a portion of the clot remains, either as a thin or thick layer lining the interior, or in the form of fragments shrunk to one side and adherent to the walls. For all practical purposes, then, recovery is complete; and, therefore, in these cases, the prognosis, as a rule, is favourable. I have, however, already mentioned that, where there has been any considerable œdema of the limb, this condition is very apt to linger, and the leg may thus remain cumbersome and troublesome for very many months; and I have already mentioned, too, that, in the gouty form of the affection, there is an especial liability to relapse, and consequently oftentimes much disappointment in the progress of the cure.

Almost the whole of the treatment of phlebitis is described in one word—rest; rest in the horizontal posture, or with the limb affected somewhat raised. When the liability to this affection is great, the most trivial causes seem to determine the formation or extension of clot. It is often started by extra exercise—an unusually long walk or slight overexertion. Even very moderate pressure on a vein, as from one leg resting on the other, will sometimes start it. And, after it has begun, the chances are that the mischief will spread to some extent, do what you will. But absolute rest is the best safeguard. For it is not only of chief efficacy in controlling the extension of the disease, but no other means are known which can be reckoned of any material value in lessening the chance of any of those accidents which wait upon phlebitis. Drugs may be employed when there are any special indications for them. When, for example, there is any evidence of gout or rheumatism, much good may come of physic, or when there are signs of other forms of constitutional disturbance, such as pyrexia. In all circumstances, measures of general hygiene should be carefully attended to. The patient should lie at rest in air as pure as possible; and, in view of the tediousness of these cases, it is often well to have him soon carried to some place where this condition can be best fulfilled. We know how phlebitis is apt to complicate the convalescence of fevers, and cases can be mentioned in which thrombosis or an attack of phlebitis has followed exposure to emanations from foul drains, in such a way as to suggest that some poison mingling with the blood, instead of continuing to disturb the whole mass, has coagulated a portion of it, and has thus been separated from the rest.

Neither can very much be done in thrombosis or phlebitis by local measures. The application of leeches in the course of the vessel has gone out of fashion. The relief they give is but temporary, and sometimes the irritation of their bites will prove mischievous. When the pain is very severe, it can be controlled by the local or general use of opium or morphia, or of something else. Otherwise, I think the most grateful application is, in the early period, a very strong lotion of acetate of lead; one part of the liquor plumbi to seven or eleven or nineteen of water. But, perhaps, the application of cloths wetted in simple water is nearly as good. Bandages at first are not advisable. They heat the limb, and otherwise increase the discomfort. But, when all signs of active mischief have subsided, when little or no tenderness remains, and the œdema is the chief trouble left, then bandages properly applied are undoubtedly very useful. Still later on, shampooing and baths of various kinds may be tried; but these should only be thought of when all risk of disturbing clots has long passed by. The baths of Aix les Bains, or Wiedbad, or the mud-baths of Marienbad may be suggested, and evidence is not wanting of brilliant cures effected by their means.

But, given a case of phlebitis, and it is not difficult to describe in general terms the prospect. At the best, it is likely to last long and prove tedious. It is not without risk to life; but a fatal issue, even from its several causes conjointly, is comparatively rare; and as time goes on, these risks diminish. But, if the patient would reduce these several risks to their lowest value, and otherwise accept conditions most favourable to his recovery, he must make up his mind to lie still for a long time.

## AN ADDRESS

ON THE

### HISTORY AND OBJECTS OF THE BRITISH MEDICAL ASSOCIATION.

*Delivered at the First Annual Meeting of the Dublin Branch of the Association.*

By ALFRED HUDSON, M.D., President.

Physician in Ordinary to the Queen in Ireland, etc.

IN occupying this chair for the few moments which remain of my term of office, my first duty is to offer you my sincere thanks for the honour conferred upon me by electing me as the first President of the Dublin Branch of the British Medical Association, and to tender the thanks of the members of the Branch to the distinguished visitors who have honoured us by their presence on this occasion.

Following the example of some of the distinguished men who have held a similar position to mine elsewhere, I shall throw a glance backwards upon the origin, objects, and progress, of the parent Association, and, to a very limited extent, I shall refer to the science it aims to advance. Such an address, while necessarily brief and fragmentary, must be of a twofold character—retrospective and suggestive. The materials I shall chiefly glean in the records of the Association, and more especially of the decade which has elapsed since its annual meeting in this city.

Having been for some years a member of the original Provincial Medical and Surgical Association, I may, perhaps, be permitted to make a few remarks on the precursor of that which is now the most numerous and powerful body existing in the profession.

I would remark, then, that much of the great success which has been achieved was due to two causes—the time and the mode of its inauguration. The time was one of wonderful intellectual activity and scientific progress. It was said by an eloquent writer of the period: “The reason of man is now more fully employed than at any former period; a vast store of mental power, a vast mass of mind, is everywhere at work; what formerly was vainly attempted by the labour of a few is now easily accomplished by the exertions of the many.” A glance at the names and works of the great physicians and surgeons of the time will amply prove the truth of this with regard to our science, so that we may say that the original promoters of the Association took advantage of that “tide in the affairs of men which, taken at the flood, leads on to fortune”. But it is due to the memory of its principal founder, Sir Charles Hastings, to state that much of its success was due to the judgment and clearness of view with which he drew up its rules and defined its objects, calculated, as these were, to advance the interests of the profession and the public, and to elevate the status, and illustrate the talents and acquirements of the provincial practitioner. This latter object was most effectually subverted by the masterly retrospective addresses of such men as Frichard of Bristol, Crosse of Norwich, Scott of Liverpool, Symonds of Clifton, Bardsley and Black of Manchester. Even now, no one could peruse these learned essays without improvement, nor without that feeling of admiration which prompted the late Sir William Ferguson to say in his presidential address: “Few physicians or surgeons of the present day would venture upon such extensive ground; but, doubtless, there were giants in those days, for they did their work well.”

All who are familiar with the annual addresses delivered during the last decade will admit that, if necessarily less comprehensive in their scope than those I have alluded to, they are marked by an equally enlightened and philosophic spirit, and justify the wise anticipation of the founder of the Association, that this retrospective view of medicine alone will stamp a considerable value on its proceedings, because nothing can be more proper than that, at stated periods, reports should be made of the advancement of a progressive science.

The career of the Association has been a continued and increasing

success. Founded forty-five years ago, and originally consisting of three hundred and ten members, the numbers have increased year by year, at first slowly, but since the present editor, Mr. Ernest Hart, took charge of its weekly JOURNAL, more rapidly, so that in the last eleven years nearly six thousand members have been added to its strength, and it now numbers nearly eight thousand members, comprising men of the first rank in the profession in the three countries; and has received and conferred honour by having been presided over by men of the highest professional status in the towns in which its annual meetings have been held, as by Sir William Fergusson, in London; Sir Robert Christison, in Edinburgh; by Dr. Stokes, in Dublin; Dr. Acland, in Oxford; and Dr. Paget, in Cambridge.

Commensurate with the growth of the Association in numbers have been the development of its work at its annual meetings, the increase in the number and interest of papers and discussions, and the improvement of its JOURNAL; the increase of the grants of money for the promotion of medicine and the allied sciences, and of its social and political influence.

Its meetings consisted originally of a single section. For several years, they have comprised from four to six, the attendance on each of which has been in proportion more numerous than that of the meetings formerly was. We had, at the late meeting in Manchester, no fewer than nine special addresses of marked ability, on medicine, surgery, midwifery, physiology, sanitary science, and psychology. Its JOURNAL, I think you will all admit, deserves the eulogy of Dr. Allen Thomson, in his address to the Glasgow Branch, that with an enormous circulation it maintains an useful and honourable place among the records of the medical literature of the time. Of the third object, I am happy to learn that the Scientific Grants Committee has this year at its disposal the sum of £400. I also learn that the Committee of Council, acting on the recommendation of the Scientific Grants Committee, have resolved that in future the Hastings Memorial Fund shall be allocated to found a Hastings oration or address, to be delivered biennially by some highly distinguished medical man, at home or abroad, who has elucidated by his researches some important point in medical science or practice.

It cannot be doubted that, by the subdivision into several sections, the power of doing scientific work at the annual meetings has been much increased; but, as Dr. Sieveking remarked (in his Address on Medicine in 1876): "An association can do little *directly* to promote science. Scientific work is rarely well done by large assemblies. The student works in the quiet laboratory, in the secluded library, or at the bedside of his patient; and though he may be encouraged by the sympathy and approval of his contemporaries, science and its results are, and ever will be, his chief reward." It has, however, powerfully contributed to the improvement of medicine as a practical art, by enlisting and embodying the labours and experience of those "silent workers who," says Sir William Jenner (Address on Medicine, 1869) "render most efficient aid, the results of their unspoken experience confirming or refuting the published assertions of the few. It is to the experience of the mass of the profession that we look for the final establishment of doctrine and of the rules of practice."

But the influence of the Association has been most decidedly felt in the improved relations of the members of the profession to each other and to the public, and the consequent increasing influence, both social and political, of the profession as a body, as well as in the promotion of that branch of preventive medicine called sanitary science.

The subjects of social reform and sanitary science, though essentially distinct, have been usually treated of together at the annual meetings under the name of Preventive Medicine, Public Medicine, or State Medicine. They were first thus grouped, so far as I am aware, by our fellow-citizen, Dr. Henry Maunsell, in an able and vigorous discourse on what he termed Political Medicine, published in 1839. I need not remind my hearers of the discourse delivered at the meeting in this city in 1867, by Dr. Rumsey, or of its effect in leading, as it did, through the exertions and influence of Dr. Stokes, to the creation of the Dublin University diploma in State Medicine.

It is to be remarked that a great impulse was given to the study of that portion of Preventive Medicine, which relates to the etiology of fever, by the offer, by Dr. Thackeray, through the Provincial Association, of a prize of £50 for the best essay on the sources and modes of propagation of the continued fevers of Great Britain and Ireland. Not that the prize essay added anything whatever to our knowledge of the subject, or was free from the confusion which pervaded all reports of epidemics of that period (and, I may add, of some of those of the subsequent Irish epidemics of 1847-9); all causes of fever, save contagion, being ignored by the writer, and all distinctions of species, as regards typhus and typhoid, being denied. Many minds were, however,

directed to the subject at this period, with the result of producing method and order where formerly all was confusion, and of placing the etiology and classification of fevers upon a sure and irrefragable basis. The late Dr. Parkes, in his admirable address in 1873, alluded to the pre-existing confusion, but added: "How wonderful is the change now. We can make, in most cases of so-called continued fever, a diagnosis as certain as in small-pox or measles; we know what to expect, and can indicate the limits within which the morbid cause acts. When I contrast this certainty with the vague, hesitating, conjectural, diagnosis of former times; when I think also of the results of this accurate diagnosis, viz., a recognition of the mode and conditions of spread, a recognition which leads at once to preventive measures, I begin to doubt whether, after all, this is not our greatest advance in practical medicine."

But we by no means limit the domain of preventive medicine or sanitation to the investigation and prevention of external or exciting causes of disease. It has a far wider scope, embracing not only the physical, but also the moral, political, and social conditions of mankind. Of the importance of national health, in a political point of view, Dr. Maunsell writes: "No proverb is more trite than that which proclaims health to be the greatest of earthly blessings; but it is even more—it is essential, as man is constituted, to the existence of anything like virtue and peace in a nation. All experience shows that human beings, when placed in circumstances which render their tenure of life especially precarious, become almost in a direct ratio with the uncertainty of their existence, profligate, selfish, and reckless of the sufferings of others." "For my own part," says Dr. Wilks (Address on Medicine, 1872), "I believe a much larger share of the conduct of mankind should come under the cognisance of the medical man. If it be his duty to have regard to man's bodily frame, and not merely to be (as Carlyle says) a body-cobbler, his function is very large, and he immediately enters into the domain taken possession of by the social philosopher, parson, and philanthropist."

Our influence in averting the too prevalent physical, moral, and social evils of intemperance; in controlling the physical education of children; in correcting the evil effects of overwork of the brain, and other evils of the advanced civilisation of the age, will at once suggest themselves as illustrations of Dr. Wilks's remark. But neither would I limit the action of preventive medicine to the antecedents of disease, or exclude it from the domain of curative medicine so termed; on the contrary, I regard the relations of preventive medicine to disease as being coextensive with our anticipations or prognosis of its access, progress, termination, and consequences. It not only recognises and wards off the external exciting causes, but foresees and guards against predisposition, whether arising from age, occupation, habits of living, temperament, constitutional states, pre-existing illness, or the material and moral surroundings of the individual. It takes account alike of the risks attendant on the evolution and development of early age, and the involution and degenerescence of advanced life, and regulates its hygienic measures accordingly, looking especially to the improvement of nutrition in the one, and to the due elimination of the products of regressive change in the other extreme. It recognises those constitutional states, whether inherited or acquired, which so frequently cause, combine with, or modify, visceral disease, as gout, struma, and syphilis; and those constitutional tendencies which Sir James Paget defines as "progressive changes growing up towards complete and evident disease; a study comprising the personal health characters, not only of those whose unhealthy constitutions are signalised in some typical form of disease, but in those also who, to the unobservant, may seem nearly well, or indefinitely ill, or, at most, locally unsound." (*Clinical Lectures*.) As a corollary to this, it investigates the state of health before the performance of operations, as with reference to the existence of albuminuria, or of intemperate habits, etc., while, by its anticipatory care of patients after operations, the mortality of these has, in the last thirty years, been reduced, according to Sir J. Paget, fully 50 per cent.

Again, preventive medicine suggests the measures necessary to anticipate and prevent secondary blood-contamination, by infection from diseased surfaces, such as those of the throat in scarlatina and diphtheria, and the intestinal ulcers in typhoid, while it averts the risks to which patients are exposed during the convalescence from these diseases, whether from the effects of disease or from injudicious management.

Preventive medicine also comprises the adaptation of the condition and work of the healthy organs to the condition of those which are unhealthy or enfeebled, so preserving what has been happily termed the balance of safety, and avoiding the too common error of stimulating an enfeebled organ (as the heart by alcohol). Of such treatment, Dr. Russell Reynolds justly observes (Address in Medicine, 1874):—"We may help a man to get through some work for which, without such

aid, he was totally or partially incompetent. We have evoked an amount of vital action that would otherwise have been impossible; but we have used up his life in doing so."

Again, the treatment of functional derangements of internal organs in so far as this is prophylactic of structural change, is, strictly speaking, preventive medicine. To two illustrations I may be permitted to allude. One is that form of congestion of the upper lobe of the lung to which young females are subject, more especially if menstruation be suddenly checked, and which, if neglected, too frequently eventuates in phthisis. The other is those hepatic derangements of which Dr. Murchison says: "I believe the day will come when, with a more perfect knowledge than we now possess of the healthy functions and of the signs of functional derangement of the liver, we shall be enabled to prevent, or to arrest at their commencement, many of the most serious ailments to which mankind are liable, and thereby to add another chapter to the volume of Preventive Medicine (*Croonian Lectures*).

And, to bring this digression to a close, probably no more striking example could be adduced of the value of the principle of preventive medicine than the influence exerted upon the intra-uterine health and future viability of the fetus by certain medicinal substances administered to the mother. I allude more particularly to the paper read at Manchester by Dr. McClintock, on "Fœtal Therapeutics"; and I would ask, does not the valuable results of the treatment suggested and detailed by him give us ground for hope that some of the predispositions to disease inherited from the parent may be successfully combated by preventive treatment during gestation? Exclusive of syphilis, I would suggest struma, phthisis, and epilepsy as the diseases more especially suited for such therapeutic experiment. It is true that its results, being negative and far distant, may seldom be realised by the experimenter; but, in such cases, as in many others, we act upon the Scriptural precept and "cast our bread upon the waters, to be found" (it may be) "after many days".

Then, to turn for a moment to the present state of what may be more strictly termed Curative Medicine, in his able and exhaustive address on the Progress of Medicine at Leeds in 1869, Sir W. Jenner made the remark that "the advances of curative medicine have been as decided as those of preventive medicine"; "that not only have sounder views of the rational treatment of special diseases, based on advances of pathological knowledge, been established, but new drugs of great practical worth have been introduced into our *Pharmacopœia*, and old drugs have been found to possess virtues heretofore unsuspected." I must refer to this address, well worthy of attentive perusal, for an enumeration of the more novel remedies then known. Time will not allow me to enumerate the many which have been since introduced, some of which have been adopted by the profession generally, while others are under trial.

Viewing these in their relation to pathological conditions, they seem to fall naturally under four heads:

1. Alteratives, viewed in relation to the several tissues for which they have an affinity, and on which they act: a knowledge which is co-related to that of the special changes to which each tissue is liable.
2. Antiseptics, in relation to septicæmia, pyæmia, diphtheria, and all diseases caused by infective germs.
3. Constructive or recuperative, in relation to excessive waste of blood or tissue, loss of balance between waste and repair, and some forms of tissue-degeneration.
4. Agents acting on the vaso-motor system of nerves, and through them upon the circulation.

Examples of each class will occur to all, and whether we regard the treatment by alteratives of the syphilitic affections of vital organs, or the antiseptic treatment of Lister, Sanson, and others; or the influence of phosphorus and the hypophosphites on enfeebled brain and spine; or the striking effect of the hypodermic injections of ergotine in internal hæmorrhages, or of that of ether in collapse from hæmorrhage, or heart-failure from other causes, or of the inhalation of nitrite of amyl in the paroxysm of angina. We may appeal to these, with many others, as justifying our faith in medicine, and our anticipation of its future triumphs. To some of these the sciolist and the sceptic may take exception, as well as to other older and equally valuable remedies, as blood-letting, counterirritation, and mercury; but these objections amount to little more than saying I will not believe what I do not understand. But, as Dr. Wood rightly remarks, "to deny as has been done the existence or value of alterative medicines because we cannot tell why mercury relieves syphilis, or why iodide of potassium cures rheumatism, is as absurd as to deny the existence of the syphilitic and the rheumatic dyscrasia because we do not know their ultimate nature" (*II. Wood, Treatise on Therapeutics*, p. 351).

In the arguments of the sceptic we seem to recognise:—1. Objections founded on denial of the *vis consequentie* of treatment. These we can, in some cases, meet by a reference to the physiological action of our remedies; in others, by their immediate and direct effects on diseased phenomena; in others, we have no better answer at present than the experience of the mass of the profession. It were needless to remind you in how many instances this experience has been eventually confirmed by a more enlightened theory; let one example suffice.

We have often been told that the received notion that calomel acted as a cholagogue was disproved by the experiments performed on dogs by Dr. Hughes Bennett and others; but still the fact remained that headache and other supposed toxic effects of bile were removed by a calomel purge. The experiment and the empirical observation would seem to be reconciled by the theory which transfers the action of the drug to the small intestine, by irritating which, says Murchison, "it sweeps along the bile before there is time for its absorption, thus causing an increased flow from the bowel without the secretion from liver being necessarily increased".

2. Some objections are of more positive character, founded on chemical or theoretic grounds, such as Dr. Brinton's argument against that invaluable remedy in cases of gastric ulcer—nitrate of silver; as the objection on similar grounds to benzoic acid in acid states of the urine, and such as some laboured attempts to prove (see Waring's *Therapeutics*, pp. 388 and 389) the inutilty of counterirritation by a mixture of fallacious reasoning and flippant ridicule (*Practitioner*, 1869). Here, again, we simply appeal to experience and wait for the explanatory fact.

3. There is the objection grounded on the secondary ill-effects of medicines. But, however just and well founded this may have been in former times, it no longer is so, since—to borrow the terse and pithy language of Mr. Simon—we have learned that "overdoctoring is an evil. Strong measures are not for trifling purposes, nor ought treatment to be allowed except where treatment is necessary". That "in medicine, as in ordinary life, it is the great test of common sense that a man seeks, and it is the great reward of observant experience that he learns to make his means proportionate to his ends" (*Art. Inflammation in Holmes's System of Surgery*).

But, lastly, the sceptic rejecting such moderate views, and relying on his own theoretic arguments, boldly predicts that certain doctrines in pathology or modes of practice can never obtain acceptance in future. In so doing, he ignores two important considerations. The first, that medicine, unlike the exact sciences, advances not directly, but in cycles, and that consequently change is not synonymous with progress. The doctrine or practice of to-day is often discarded to-morrow, only to be again accepted for better reasons and as founded on a surer basis. The illustration of the employment of digitalis in cardiac dropsy will occur to every mind and needs not to be dwelt upon.

But, again, we may remark that the history of medicine, as of other arts and sciences, abounds with vaticinations which have been falsified by advancing knowledge; and with problems pronounced dark and insoluble, which have been solved by its increasing light. Such vaticinations appear to me to be of two kinds, the one due to ignorance or imperfect means of research, the other to the inability to reconcile the novel doctrine or practice with existing theory. Perhaps I may be permitted to mention briefly one or two examples of each.

Cabanis, the author of a classical work on the revolutions of medicine in the beginning of the present century, pronounced the minute anatomy of the brain as not only badly capable of being ascertained by the scalpel or microscope, but as "rather an object of physiological curiosity than of medical utility, and at present wholly useless and likely to remain so". At a more advanced period, Sir Astley Cooper was, like all his contemporaries, so ignorant of the pathology of constitutional syphilis as to teach that it never attacked the vital organs, as the brain, liver, or kidneys. In the retrospective address of 1840, the able orator (Dr. Scott) characterised the doctrine that "the material of contagion is composed of organic matter, and not only an organic, but living matter, as startling, and based on a few unsatisfactory analogies". Lastly, not to multiply examples, that profound physician and psychologist Dr. Prichard, in his retrospective address of 1835, says: "How strange does the following proposition of M. Broussais appear to those who have reflected on the obscurity of the subject. The cause of moral perversion and of suicide in cases of mental derangement consists always in irritation of the trisplanchnic apparatus, and especially of that belonging to the stomach acting on the brain." Doubtless, the hypothesis was, like others of the same author, both too general and too exclusive, but that it contained a germ of truth, daily experience proved; so that Sir W. Gull, in his address in Medicine at the Oxford meeting, remarks that, "as there is no explanation of laughter when the axillary nerves are tickled, so there seems to be none of the morbid fears which

oppress those who are the subjects of some affections of the colon, and who weary our patience with their doleful complaints. Yet, surely we have no more reason to deny the one than the other, though we must at present refer both to some ultimate fact of our natural history."

Now, according to Dr. Fothergill, this is no longer an ultimate fact, but is explained by the fact that the posterior cerebral lobes are fed by the vertebral arteries, these deriving their nerve-supply from the same cervical ganglion, which is in intimate relation with the thoracic ganglia and the splanchnic nerves which supply the abdominal viscera. "Thus," says Dr. Fothergill, "we now comprehend how disturbance in the abdominal viscera can produce melancholia without the intellect being obviously affected. There is anæmia of the posterior cerebral lobes from arteriole spasm, the result of distant irritation."

I would remark, in passing, that there is a possibility of the progress of therapeutics being for a time hindered rather than forwarded by advances in science. One danger arises from relying too much on the results of experiments on animals. Valuable results have, no doubt, been obtained from these, more especially with regard to the physiological action of medicines and to the antagonisms of certain poisons; but, as Dr. Matthews Duncan remarked in his able address on Obstetric Medicine in 1874: "There is a variety of circumstances which seem to indicate that the lower animals are not subject to exactly the same laws in these matters as man is, and certainly there must be great caution exercised in arguing in human pathology from the analogy of the lower animals."

Another danger may arise from an undue reliance on the mechanical aids to morbid anatomy and physical diagnosis which abound in the present day. Some of us may remember how, shortly after the introduction of the stethoscope, a too exclusive attention to the physical signs of diseases led not unfrequently to imperfect diagnosis both of the local mischief and of the constitutional state, and certainly a large amount of skill in the use of the more modern appliances is compatible with insufficient comprehension of subjective symptoms, and consequently with imperfect diagnosis. A similar remark holds good with regard to the microscopic study of morbid structure, a profound knowledge of which is also compatible with imperfect acquaintance with the disease which led to it. I would by no means undervalue those mechanical aids, far from it, but "it is well when the tool sharpens the wits that use it, and teaches its pupils in the end to dispense with its services". This reliance on physical diagnosis and its instruments becomes an effectual hindrance to true progress when conjoined with what Dr. Acland, in his presidential address in 1868, happily termed "reckless negation of the accumulated experience of our race". He well observes that "we are superior to our fathers in the means at our disposal, and in the positiveness with which we can up to certain points enunciate our results. But we ought not to overlook the fact that, with these positive gains, we are subject to contingent losses, and that in an epoch of details and comparatively facile methods of inquiry, the greater qualities of patience and reserve may be lost to those who are not themselves original investigators."

Another hindrance to progress is that produced by what I might term waves of fashion, which not only drown our judgment when fashion is at the flood, as when some doctrine or practice is carried to excess—like the much abused apophthegm of Graves, "Let my epitaph be 'He fed fevers,'" or the alcoholic treatment of Todd—but leave us stranded in doubt and uncertainty when it is at the ebb, as when blood-letting, once too indiscriminately employed, is indiscriminately neglected, for no better reason than that its disuse is now the fashion, the only arguments against the *use* being those drawn from the former *abuse* of this remedy.

I shall allude to but one more of the besetting sins of the day, which seems the natural outcome and result of self-confidence, and neglect of the labours of others. It is the unnecessary and increasing accumulation of dry facts, by which, as has been remarked, the progress of science is impeded like as that of an army by its baggage. The age of hypothesis is past, but that mental operation is now often wanting by means of which we advance from the observation and collection of facts to the laws of phenomena, and onwards to the theory of causes. Far too much of our periodical literature is occupied with the details of trite and familiar cases and observations by writers, of whom it might be said that they resemble the fool in "As you like it", of whom Jaques says—

"And in his brain—  
Which is as dry as the remainder biscuit  
After a voyage—he hath strange places cramm'd  
With observation, the which he vents  
In mangled forms."

I have said that the Provincial Medical Association was fortunate in its inception; and I think we may say the same of our own Branch

of the British Medical Association, which, thanks to the exertions of our able and energetic honorary secretary, has already established intimate and most friendly relations with the parent body, a proof of which we have in the presence of its distinguished President, and the able editor of its JOURNAL, among us to-day, giving "a testimony" (to use the language of the President in accepting the invitation to attend), "of readiness to strengthen the new and important bond which the Dublin Branch forms between the members of our profession in England and Ireland".

I am sure that these feelings will meet with a hearty response in the breasts of all our members, and that each will be anxious to support those interests, and promote those high aims, which the Association has in view. And let us remember that, while working for the Association, we shall be upholding the character of the Irish Branch of the profession, a duty so eloquently enforced on the members of the Royal Irish Academy by Professor Jellett, that I shall make no apology for quoting a few words of his address: "God forbid that we should ever forget that the place which our country holds among nations must be fixed by the labours of her children, that their success is her glory, that their defeat or dishonour must fall darkly upon her. If this thought be irrelevant, it has in itself that which must command our attention whatever else may engage it. If it be selfish, it is selfishness so enlarged, so purified—may I not say so noble?—that it cannot fail to exalt the mind where it is found. And Truth herself will not condemn us, if with our devotion to her, a thought of patriotism shall mingle. It will not degrade her worship, nor will it render us unfaithful. We shall not love Truth less because we love our country too."

And surely, if any other stimulus to exertion were needed, we have it in the traditions of the Irish School of Medicine, and the memory of the illustrious band whose fame is for ever associated with it—of whom but one, Sir D. Corrigan, the last but not the least in fame and honours, now survives among us. Of men "whose high ability and conscientious worth", said the late Lord Carlisle on a public occasion, "have heretofore rendered the medical profession in this country illustrious, and have attracted to this city, from all shores, crowds who deemed it a privilege to sit at their feet and to profit by their lessons". And may I not add that we have it in the example of one who has so recently passed away from among us—of him to whom Lord Carlisle alluded by name as "that living light of the profession, Dr. Stokes"—who, though dead, still lives in his living works, in the widespread influence of his clinical teaching, and in the grateful memory of the numerous pupils trained, by his precept and example, to the knowledge and love of their profession, and of the many friends and colleagues to whom he was endeared by his high principles, scrupulous honour, and kindly consideration. Nor will he soon be forgotten by those members of the Association who visited Dublin in 1867, when he presided so worthily over its annual meeting.

The name of Stokes involuntarily suggests that of his great colleague, to whom so graceful and deserved a tribute was lately paid in this College Hall. Colleagues they were, in more than the ordinary sense of the term, for no two men were ever more fitted to be thus associated, inasmuch as in their mental gifts and character they were each the complement of the other. During their lives—and, to a great extent, to the present time—their names were constantly coupled as "Graves and Stokes of the Meath Hospital", as the joint authors of valuable papers in the *Dublin Hospital Reports*, and as the reformers of clinical teaching, and among the foremost of clinical physicians.

And if they differed in their type of mind, they differed in their fate. The man of eagle glance, of rapid intuition, and ardent temperament, died in the meridian of his powers, ere his brilliant theories and many valuable practical suggestions had been generally accepted by the profession. The other, the patient worker and profound thinker, was happily spared to beyond the "three score years and ten", long enjoyed an abundance of the blessings "which should accompany old age", and finally, left the stage of this world amid the mingled admiration and regret of his contemporaries in this and other countries.

Gentlemen, I feel that I have trespassed too long on your time and attention. I shall, therefore, add to my gleanings but one more—a passage from an eulogy on the lives and work of some of the master minds of a former generation, which I regard as peculiarly applicable to both my great teachers, and as conveying a salutary lesson to ourselves.

"And as I endeavoured," says Dr. Robert Ferguson, "to track the workings of master minds, I observed that each felt the insignificance of man amid the might of Nature, and that he who looked most loftily tempered his gaze with such humility as to see nothing in his magnificent acquisitions but a few shells gathered on the shores of an un-

known ocean. And this estimate of human powers, I thought, should be a bar against the indulgence of all those envyings and heart-burnings that too often embitter the professional career. And then, if I followed them into the recesses of their study, I learnt that knowledge not only fills but purifies the understanding; that, in their communing with Nature, their minds had insensibly imbibed her influences; that their industry, like hers, was calm, unobtrusive, and incessant—an instinct rather than an effort, and its reward the gratitude of mankind. If their lives were chequered with the good and evil of our lot, I saw that they sustained the trials of prosperity with honour, and the sharp strokes of adversity with dignity. The consciousness of duties discharged, and the occupations of their career, alleviated private griefs; while the contemplation of the serenity and steadfastness of Nature prepared the heart for those higher and nobler thoughts without which there is indeed no repose."

Let me add, we have reason to know that such thoughts were entertained by both, and consequently that it may be said of both—

"They rest from their labours, and their works do follow them."

## IODOFORM AS A LOCAL APPLICATION.

By WYNDHAM COTTLE, M.A., M.B. Oxon., F.R.C.S., M.R.C.P.,  
Senior Assistant-Surgeon to the Hospital for Diseases of the Skin,  
Blackfriars.

At a time when many new remedies are constantly being brought to the notice of the profession, and often lauded as of extraordinary virtue, but, after a longer and more extended trial, disappear from practice and are heard of no more, I should feel some disinclination to call attention to a not widely known drug, had not so high an authority as Mr. Berkeley Hill already done so. But, indeed, iodoform scarcely comes within this category. It has been in extensive use for some time by many surgeons, and, during the last two or three years, I have experimented with and prescribed it largely and with the most encouraging results. First discovered about the year 1824 by Serullas, its properties have long been known to chemists. It is readily obtained by adding an alcoholic solution of potash to tincture of iodine, and crystallises as a yellow lustrous coarse-grained powder of a peculiar pungent penetrating odour. It stands in the same relation to its analogues chloroform and bromoform as hydriodic acid does to hydrochloric and hydrobromic. It may be regarded as chloroform ( $\text{CHCl}_3$ ), in which the three atoms of chlorine are replaced by three of iodine ( $\text{CHI}_3$ ). It also forms substitution compounds with chlorine and bromine. It is sparingly soluble in water and glycerine, less sparingly so in alcohol and warm oil, but readily soluble in ether, and to a still greater degree in chloroform.

Two years ago, I made solutions of iodoform in alcohol and ether; but, as the liquid rapidly became of a dark iodine tint, I feared that some substitution-product or decomposition might take place in the liquid, and generally employed the solution in warm oil. Chloroform is, I believe, its most effective solvent. Iodoform can readily, by trituration, be made into an ointment with either lard or vaseline, and its odour, in some measure, disguised by the addition of essential oils, as the essential oil of almonds. As a powder, it can be employed alone or diluted with fullers' earth, magnesia, or tannin; the last mentioned body having the peculiar property of, in some measure, removing its powerful and disagreeable odour.

In the form of suppositories, iodoform has been employed as a local anodyne, but with no marked benefit, as I understand, though I have no experience of it in this respect. As a powder, it has been extensively applied to cancers and venereal sores; and I have to thank my friend Mr. George Perry for calling my attention to its use in these cases, when I was at once struck by the very remarkable results produced. Its action can, perhaps, be best shown by stating its effect in the several affections in which I have applied it.

**Venereal Sores.**—Iodoform seems to act equally well in these cases whether they are ordinary venereal sores or genuine hard or soft chancres, and whether situated beneath the prepuce or on other parts. Its action seems to be that of a topical irritant in some measure, and it may set up too much local action, if applied to an inflamed sore or wound, as Mr. Berkeley Hill points out in his paper on the subject in the BRITISH MEDICAL JOURNAL of January 26th, 1878. It should not, therefore, be applied to a sore when acutely inflamed.

From records of cases, I find that twenty cases of venereal sores classed "primary syphilis," which occurred in practice in their chance sequence and without any effort at selection, were treated by me by the ordinary local methods, with or without internal remedies. These were, on an average, rather more than twice as long under treatment,

before the sores were completely healed, as the same number of other cases, taken in a similar way and under precisely similar conditions, in which the only remedial measure was the topical application of iodoform. These results are the more encouraging when I add that, in patients so treated, there is diminished risk of buboes and lessened constitutional depression from the more rapid progress of the cases. It seemed to me also that the sequence of secondary syphilis was less frequent. Iodoform acts particularly well in cases where there is a disposition to slough.

**Buboes, Syphilitic Ulceration, etc.**—In practice, buboes that are most tedious and indolent are of frequent occurrence. They often have deep and extensive sinuses and fissures that show little or no inclination to heal, and sorely tax the patience both of the surgeon and of the patient. I have found that these cases almost invariably rapidly granulate, contract, and cicatrise by the application of iodoform; and the same obtains in the late forms of syphilitic ulceration. A man, about twenty-eight years of age, with serpiginous ulceration of syphilitic origin, which, first breaking out in the groin, had extended over the lower part of the abdomen and upper part of the thigh, and was for over a year under treatment, with every likely remedy, including change to the seaside. In this case, nothing seemed to check the morbid process, or to set up healthy action, till iodoform was called into requisition. Under its use, the ulceration had almost healed, when the patient was lost sight of. I have often injected the deep sinuses that may result from buboes, etc., with a solution of iodoform, and have frequently found them mend under this treatment when other means have failed. As an injection in gonorrhoea, in the few cases in which it was tried, it seemed to set up so much inflammation, that I abandoned its use.

**Chronic Ulcers.**—In ulcers about the lower extremities, and indeed elsewhere, I have formed a very high opinion of iodoform as a therapeutic agent. I have used it largely both at the hospital and in private. Ulcers that have remained open for years, and on the treatment of which much care and skill have been expended, often close in a few weeks under its influence; but the same caution must be repeated as in the case of venereal sores. It will only irritate the actively inflamed wound. It is the indolent ulcer, from whatever cause it may arise, whether from varicose veins, malnutrition, syphilis, or injury, that is especially benefited by iodoform. Repeatedly, under its use, I have seen a surface, glazed or oedematous, rapidly take on healthy action, granulate, and heal, and this where other measures have been tried for months, or even longer, without effect. Often, too, the pain that so frequently accompanies these ulcerative processes ceases after iodoform has been applied for a few hours.

**As a Parasiticide.**—In many cases of ringworm of the scalp of long duration, and which had been before the subjects of much and careful treatment, I have prescribed iodoform in the form of an ointment. In several of these, speedy improvement ensued, spores being no longer to be found and the parts returning to a state of health; but I met, in some instances, with considerable difficulty in inducing the parents to apply the remedy, on account of its powerful odour. It set up no violent inflammation, and I hope it may prove an useful adjunct to the means at our disposal for combating that disease.

Chloasma quickly yields to this agent; but, again, its odour is an insuperable objection to its employment in the treatment of this disease. The results that I obtained from its application in several cases of sycosis were not encouraging, as it seemed to give rise to undue irritation. In the form of powder, I have used iodoform in several cases of lupus with ulceration and rodent ulcer; but my observations on its conduct in these cases have not been at present sufficiently complete to warrant a definite opinion.

A word, in conclusion, as to its mode of application. If used as a powder, iodoform should be dusted on the ulcerated surface, and a piece of dry lint, or lint soaked in a weak solution of carbolic acid, may be laid over it, and this process repeated night and morning. Undiluted, I have often found it apt to produce irritation and pain, and, therefore, generally prescribe it mixed with equal parts of either fullers' earth or tannin. As a parasiticide, I have used it as an ointment with about twenty grains to an ounce of lard, and have directed it to be applied twice daily. Such an ointment spread on lint is a convenient mode of application to a wound or ulcer, and its employment in this form prevents the risk of dropping this disagreeably smelling drug on the patient's clothes, etc. If an ointment of the strength named cause inflammation or pain, it may be diluted. I am also in the habit of ordering iodoform in combination with a salt of mercury, etc., with satisfactory results. So also it may most conveniently and easily be applied by painting the part with its solution in alcohol, chloroform, or ether, as Mr. Hill describes.

There are two drawbacks to the use of iodoform. The first is its extremely disagreeable odour, which, unless it is carefully covered over,

scents the room in which the patient is; the second is its high price. The latter, however, would soon be reduced, if any considerable demand arose for it.

## A SUCCESSFUL CASE OF SPLENOTOMY.\*

By DR. A. MARTIN, BERLIN.

THE great progress of modern laparotomy, which we all agree we owe principally to the energetic initiative of our English brethren, is sufficiently proved to encourage us to-day to proceed to the removal of growths and degenerate abdominal organs which but a short time ago seemed to be a *noli me tangere*. The benefit of this we gynecologists particularly enjoy, as only thereby the removal of those genital organs which seem to be singularly exposed to degeneration has become common property among us. Looking at the results of ovariectomy, we can boldly proceed to the removal, if it become necessary, of any other abdominal organ, provided only that this step do not injure irreparably the bodily system. And here only begins the great difficulty, namely, to know what organs the body can lose without fatal result. Experiments on animals cannot be accepted as the best evidence in the settlement of this question; much more do we owe to those accidents which destroy or wholly arrest the function of the organs of the abdominal cavity. If this can be proved in a convincing manner, the removal of degenerate organs or parts of them can be a question only of improved surgical manipulation.

An organ, the function of which has remained a problem to physiologists, the *spleen*, seems to have been always protected against surgical interference because of its unknown value in the corporeal system. But there are partial and even entire interruptions of the function of this organ, chiefly from traumatic causes, which show that we can easily spare it from the body; and, as far as I have examined the literature of the subject, these accidental cases encourage us to make a favourable prognosis when surgical interference becomes necessary. And bold surgeons have taught us already that this extirpation can be done. The results of these cases have not, indeed, until now been very favourable to this extirpation, as out of nine patients only three recovered from the operation. But if we examine the causes of the six failures, we find that one died of pyæmia; two sank under the influence of shock; while the remaining three died of bleeding, one upon the operation table, and the two others a few hours after the operation. The three survivors recovered rapidly, and, as far as it is stated, enjoyed good health, suffering from no disturbance of digestion or other sources. It is much to be regretted that observations were not made on them as to changes in the blood. At all events, it seems to be ascertained that we can live without the function of the spleen.

Concerning the operation itself, in all these cases the organ has been considerably enlarged; by such enlargement, the spleen always grows towards the median abdominal line, and in no instance was there any difficulty noted in finding the diseased organ or in removing it through the abdominal incision. Surely, the difficulties of the operation are all accumulated in the ligation of the splenic vessels, which must be cut in the most dangerous neighbourhood of the stomach or of the pancreatic glands. In both cases, it is evident that the ligatures are likely to slip, or to injure to a fatal degree the functions of these organs. If, then, besides these dangers, the vessels are enormously distended with blood during the operation, we need not suppose that these splenic arteries and veins are particularly fragile if the ligatures cut through when tightened and come away. Nor should we be much surprised if the ligatures should slip, as we cannot put them far enough from the ends of the divided vessels; and just in these parts that would seem very necessary, as the blood from the great aorta runs directly into them with enormous force. Billroth is particularly afraid, it seems, of injuring the pancreatic gland, and concludes from his case, in which the ligature slipped off the artery two hours after the operation, that, in spite of the dangers resulting therefrom, we ought to tie the ligature even around a part of the pancreas, in order to secure the arteries and veins. Péan has fixed the ligature like a pedicle in the wound; others have taken the whole of the vessels in one; while others have secured the vessels singly. I think we should act every one according to his own experience, and that the method of treatment in every instance has to accommodate itself to particular circumstances. As far as these differ, the probability of the result differs. This evidently is proved by my own case, in which splenotomy was greatly facilitated by the single circumstance that the organ had left its usual place and was wander-

ing about in the whole abdominal cavity, being suspended only by a pedicle which contained the elongated splenic vessels.

The patient, a poor hunchback woman, thirty-one years of age, menstruated abundantly at eleven. At the age of twenty-one, she suffered for a short time with rheumatism, and since then with palpitation of the heart. She has been twice confined: first in 1871, when forceps were used; secondly in 1875, spontaneously, though her pelvis was narrowed in consequence of early rickets. In her last childbirth, which I had to witness in the Royal Maternity of Berlin, she suffered from lochiometra, in consequence of ante-flexion of the puerperal uterus, which began the ninth day after confinement. Soon after her dismissal, she returned to the hospital to obtain relief from intense pain in the groin, which began as soon as she undertook the duties of her previous occupation, that of a laundress. By-and-by, the symptoms of endocarditis became intensely marked, and at the same time a wandering spleen was diagnosed. This wandering spleen at that time did not inconvenience the patient at all, as there was no soreness or tenderness, and she willingly appeared at the clinics of the different schools of Berlin. Notwithstanding the great attention paid to her in these clinics, her general health did not improve; especially, since her last confinement, chronic metritis and prolapsus of the anterior vaginal wall had developed to a high degree. Although she was treated in nearly all the clinical offices in the city, she became worse, and in time was hardly able to walk about. From the beginning of the year 1876, she felt other pains than those of the prolapsus and of the metritis, and attributed them to the wandering spleen. At last, she resorted also to galvanism, which for some time diminished the pains; but, during last winter, she obtained but little relief from it, and could obtain no rest from her pains until she had taken enormous doses of morphia. She also came to my ambulance, complaining less of her menorrhagia and the prolapsus than of the severe pains in the spleen, which she diagnosed perfectly well herself. Repeated microscopical investigations proved the constitution of the blood and the number of the red corpuscles and their relation to the white ones to be quite normal, at least as far as could be ascertained by comparing the specimens with the blood of healthy persons. The corpuscles themselves were absolutely healthy. There could be no doubt as to the nature of the wandering tumour in the abdominal cavity. It was strikingly evident, as well from the volume as from the form, that the tumour felt immediately behind the very thin abdominal walls was the spleen. The hilus could be easily recognised, so also the borders of the tumour, which could not be mistaken; while the whole organ seemed not to be enlarged. Under percussion, the normal place of the spleen was empty immediately after the patient had been walking; but, after some hours' rest in bed, the dulness in this region returned. After she had walked to and fro for some time, and after pressing over the abdominal wall, the top of the spleen came down to the pelvic brim, so that it could be touched *per vaginam*. Without difficulty, it could be pressed down in the pelvis alongside of the uterus.

As the pain, which was constant and intense, and which continued even when the patient herself seemed unconscious from chloroform, could not be diminished by drugs or any other means, I thought I was justified in delivering the poor woman of the organ, especially since it was probably in a state of degeneration, though I was not, through the changes, able to satisfy myself as to this question. The operation of extirpation seemed the more justifiable, since I knew, through the successful cases of the other authors, that the removal would not necessarily endanger the system. I therefore proposed the operation of splenotomy to a council of medical friends, and, as they endorsed the step, I proposed it to the patient herself, adding at once a statement of the dangers of the operation. In despair, she agreed at once to undergo it, and I had some difficulty to convince her that we must wait until after the next menstrual period.

On May 13th, 1877, I performed the operation of splenotomy, observing most accurately the antiseptic method of operating. Before the patient was placed on the table, the spleen was pressed into the median line. This being done, chloroform was given. The incision, which was in the median line, was about four inches in length, extending from the umbilicus downwards. The walls of the abdomen were extremely thin. Under the peritoneal opening, the omentum presented, but the spleen had disappeared; after some difficulty, it was found in its normal place. I was astonished to find how difficult it was to bring the organ out of this position and through the incision. The hilus was occupied by a group of vessels, which seemed to be quite separated from each other and to run free of all connections with neighbouring organs a distance of about four inches. The group next the lower surface of the organ contained one large artery. This I tied as firmly as possible with a silk ligature. Then I took the middle group, containing some arteries and the splenic vein,

\* Read in the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

which was about the size of a thick goose quill. The ligature was carried around it in the same manner as in the case of the other vessels. While ligaturing the third group, the silk broke, wounding a small artery. In a moment, a hæmatoma was formed by the blood effused into the peritoneal layer around the vessels. I now tied the vessel further from the spleen, and stopped all bleeding completely. I next cut through the vessels and took away the spleen. Although the bleeding had ceased, I surrounded the vessels with a thick silk ligature, and fastened the whole once more. After this, there was no bleeding whatever. After cleaning off the effused blood, I dropped the pedicle, which had commenced to swell most fearfully, back into the cavity. This being quite clean, I closed the abdominal walls and covered the wound with antiseptic dressing. Twenty-eight minutes after the operation was commenced, the patient awoke in her bed feeling quite comfortable.

The removed organ was only a little larger and heavier than normal; it was densely covered with star-like old and recent superficial cicatrices of perisplenic inflammation. The parenchyma itself was not changed, nor was the blood the vessels contained pathologically changed.

The patient recovered without any febrile reaction. Being accustomed to the use of morphia, she received, during the first three days, several doses *per diem*. For the first day, she took only small pieces of ice. On the second day, the bowels began to act spontaneously; then she had beef-tea and wine. On the fifth day, she felt so well that, during the momentary absence of the nurse, she left her bed to look out of the window. On the fourth day, the bandages were changed under carbolic spray, the wound having healed almost completely *per primam intentionem*. On the ninth day, she felt so well that I could not detain her in bed any longer, and on the eleventh day I found her sitting in the sunlight at the door of my clinic. The patient felt extremely well; the old pains, which I believe to be caused as well by the chronic inflammation as by the tension of the peritoneum by the organ, had disappeared, nor were any functions of the body disturbed. In different preparations, I examined her blood microscopically, and sometimes in these examinations I was favoured with the kind assistance of Dr. Gravit, of Virchow's Pathological Institution; but we found no alteration of the corpuscles, either in form or behaviour, nor in their relative number, nor was the fluid changed from its state previous to the operation. During the third week, the patient suffered serious indigestion from improper food. The menses were postponed six weeks, as has frequently occurred before; and the flow was not so profuse as during the former periods. I was the more satisfied by the rapid recovery of the patient, for there thrombi were surely to be expected to form in the long splenic arteries, and I feared serious trouble therefrom. Nevertheless, no symptoms of any danger could be discovered, and three weeks after the operation the patient returned to her work, and at every opportunity hastened to show herself to those who had previously treated her.

This, gentlemen, is the case I have to report to you. It proves undoubtedly that we can exist without the spleen—that splenotomy does not change the constitution of the blood. Besides this, the case proves that, as soon as the tying of the vessels is facilitated, the operation of splenotomy will not be such a dangerous measure as it has been thought to be, and especially when it is done under the antiseptic regimen, which in Germany at this time would not be omitted in this operation.

#### CASE OF OSTEO-SARCOMA OF TIBIA, RECURRING IN STUMP OF THIGH, AND PROBABLY AFFECTING THE LUNG.

By JOHN EWENS, L.R.C.P., L.R.C.S.E.,  
Surgeon to the Hospital for Sick Children, Bristol.

THE BRITISH MEDICAL JOURNAL of December 29th, 1877, contains a report of osteo-sarcoma of the femur, with death from subsequent deposit in the lung, read before the annual meeting of the Association in August last, by Mr. Heath of Manchester. As the following case seems to be in some respects somewhat antagonistic to the conclusions arrived at by Mr. Heath, in connection with the opinion of the late Sir W. Fergusson, it will not, I think, be without some practical interest.

A boy, aged 8, was admitted into the Hospital for Sick Children, Bristol, in May 1876, with a large tumour of the upper extremity of the left tibia. The history given was that, some weeks before, he had been struck by a stone flung by another boy, and that he had walked some distance in the snow, and got chilled. The very rapid growth and general appearance of the tumour led to the diagnosis of malignant

disease, and that nothing but prompt amputation far beyond the limits of disease could afford the least chance of saving life. The inguinal glands, though more distinct than usual on account of the extreme emaciation, did not appear to be diseased. There was no abdominal tenderness, or evidence of any visceral disease. Amputation was performed by the circular method about the middle of the thigh. The wound was dressed with carbolic oil, and the arteries tied with carbolicised catgut. Rapid union of the deep structures occurred by first intention, and the patient was discharged quite well in about a month. The whole of the upper third of the tibia was involved in the malignant growth, which also extended into the joint (but did not invade the femur) and for a considerable distance down the cancellous tissue of the bone. The soft parts were also extensively involved. Unfortunately, the hospital cards containing detailed notes as to circumference of the tumour, etc., have been lost or mislaid.

On October 14th, the boy returned with a tumour, of the size of a small orange, on the inner and anterior side of the stump, which, he said, had been growing about six weeks. It was not very painful, and was somewhat movable, and probably had deep attachments. He said it had commenced on the surface. The inguinal glands were not tender or materially enlarged. His general health was wretched; hurried respiration; quick pulse; leading me to suspect extensive disease of the lung. On examination, dulness with extensive crepitation over the whole of the posterior aspect of the chest was detected. The only question remaining was the propriety of removal of the stump at the hip-joint, but this was negatived after further careful examination of the amputated limb (which is now preserved in the museum of our medical school), the femur being found free from disease; and the inference was that, as the whole of the diseased structures had been removed, the malignant cachexia was so decided as not only to reproduce the disease in the stump, but most probably the lung-affection was of a cancerous nature. He was therefore discharged, and lived about a month. I visited him about a week before his death, and found that the tumour had rapidly increased in size and appeared as though it would soon ulcerate; but this did not occur, and the chest-disease was the immediate cause of death. As he lived ten miles from Bristol, no *post mortem* examination could be obtained.

It appears to me that this case proves an exception to the rule laid down by Sir W. Fergusson, referred to by Mr. Heath, "that large malignant growths, springing from the long bones, do not, after amputation, if the whole of the diseased structures be removed, return in the stump, but at some distant part; and, therefore, it is not necessary to amputate above the knee in case of the tibia, or at the hip-joint in case of the femur."

Now, in the case I record, it is obvious that the disease did return in the stump—whether prior or subsequently to the lung-disease I cannot say—and that it progressed with a rapidity which would have speedily of itself proved fatal; and yet it was my own opinion, and that of my colleagues, that I operated far beyond the limits of disease then apparent. Hence it would seem to be impossible, with certainty, to promise immunity from a return of this formidable disease, whilst in suitable cases we must not hesitate to amputate.

Mr. Holmes (*Surgical Treatment of Children's Diseases*) in the course of his observations on this subject, says (second edition, page 334): "Usually, however, the case proceeds very differently; the malignant deposit reappears in the course of a few weeks after removal of the limb, either in the glands or in the interior of the body."

Mr. Erichsen (*Science and Art of Surgery*, seventh edition, vol. II, page 207), in connection with this subject, says: "I believe that return is much more speedy and certain after amputation, in the peripheral than in the central form of malignant disease of bone, provided that in the latter the whole of the bone has been removed; this is due to the more extensive contamination of the soft parts in the former than in the latter case." Again, "If the limb be removed in the continuity of the diseased bone, there must necessarily be a great probability of a very rapid return of the morbid action in the stump; and this probability amounts to a certainty in those cases in which the disease is central, and in which the whole of the medullary canal and cancellous structure are implicated and infiltrated with cancer. In cases of peripheral disease, this return in the same bone may not take place"; but, as there can be little certainty about the matter before operation, he advises removal at or above the next joint. Further on, he observes: "In some forms of malignant bone-disease, however, the muscles inserted into the affected bone often become speedily contaminated, and this contamination may spread widely through the substance or along the sheath of any particular muscle. Hence, I think the rule in these cases should be to amputate not only above the diseased bone, but, if practicable, above the origins of the muscles in the neighbourhood of the disease."

As the disease did not return either in the glands or the bone, and the site of the recurrent tumour corresponded to the cut end of the sartorius, it appears to me to be an example of that form described by Mr. Erichsen, of infiltration of this muscle spreading upwards from its tibial insertion. Of course, his suggestion to amputate "above the origins of the muscles in the neighbourhood of the disease" could not in this case be adopted. It is very unfortunate that no *post mortem* examination could be obtained, as it would have cleared up any ambiguity as to the condition of the internal organs and the exact relation to the bone of the tumour in the thigh.
